8TH INTERNATIONAL CONFERENCE FOR PHOENIXES ON EMERGING CURRENT TRENDS IN ENGINEERING AND MANAGEMENT

ICONIC 2K25

PROCEEDINGS

VENUE : AUDITORIUM

MARCH : 21ST & 22ND

IEEE COMPUTER SOCIETY

IEEE PANIMALAR ENGINEERING COLLEGE

PANIMALAR ENGINEERING COLLEGE

Jaisakthi Educational Trust, An Autonomous Institution & Affiliated to Anna University

PREFACE

Dear Delegates and Guests,

The organizing committee is extremely privileged to welcome our distinguished delegates and guests to the 8th International Conference for Phoenixes on Emerging Current Trends in Engineering And Management (PECTEAM 2K25) organizing Conference on International Conference on Intelligent Computing (IConIC 2K25) which will be held from March 21st & 22nd, 2025 in Chennai, Tamil Nadu, India.

IConIC is well supported by the IEEE Madras section, CSI, ICTACT, ISTE, and IETE. The objective of this conference is to bring together the numerous problems encountered in the current as well as future high technologies under a common platform. It has been specifically organized to congregate international researchers and technocrats for presenting their innovative work, and share and gain knowledge to have a proper insight into the significant challenges currently being addressed in various fields of Computing and Expert Technology. The conference proceedings have a complete track record of the papers that are reviewed and presented at the conference. The principle objective is to provide an international scientific forum wherein the participants can mutually exchange their innovative ideas in relevant fields and interests in depth through discussion with peer groups. Inward research, as well as core areas of Computing and Expert Technology and its applications, will be covered during these events.

The conference has received 1153 papers all over India and abroad from various institutions in different domains, out of which 425 papers are selected for presentation. The submitted papers were peer-reviewed by the external reviewers and an advisory board based on the subject of interest and selected on the basis of originality, clarity, and significance in line with the theme of the conference.

It is guaranteed that a high-quality program will be conducted as the conference will be graced by an unparalleled number of professional speakers from multidisciplinary fields, both from India and abroad.

We would like to thank the chief patrons, patrons, conveners, organizing committee members, and advisory members for their immense help, motivation, constant cooperation, and continuous encouragement for the conference. We deeply appreciate the editorial board for their wonderful editorial service for the successful outcome of this proceeding. We are very much grateful to all those who have contributed both at the front desk and backyard to make IConIC an astounding success. IConIC, featuring high-impact presentations, would be enriching and undoubtedly a unique, rewarding, and memorable experience being hosted at Panimalar Engineering College, Chennai, India.

Dr. S. MALATHI
Convener

PANIMALAR ENGINEERING COLLEGE

Jaisakthi Educational Trust, An Autonomous Institution & Affiliated to Anna University

MESSAGE

Dr. P. CHINNADURAI, M.A., Ph.D.,

CHIEF PATRON

Dear Delegates,

It gives me immense pleasure to welcome you all to Panimalar Engineering College, a unique Engineering and Research Institution, which commits itself to progressive research in various disciplines of Engineering and Management.

In this modern industrial world with global challenges on continual improvement, innovative and result-oriented research is invariably essential in all fields of activities. The aura to propel quality research for knowledge dissemination necessitated us to organize conferences, symposiums, etc. **PECTEAM** is one such novel initiative and the resounding success of PECTEAM 2K24 encouraged us to organize similar programs with special emphasis on newer areas of research.

PECTEAM 2K25 will deliberate on the 8th International Conference on Intelligent Computing (IConIC 2K25) on the 21st and 22nd of March 2025.

I wish that the unique structure of PECTEAM 2K25 allows for meaningful interaction and fruitful debates between the academic and industrial communities on the emerging technologies and challenges in Engineering and Management. We are confident that such a gathering of top researchers and industry leaders should result in novel research and collaborative projects. I take this opportunity to appreciate the organizing committee members for their dedication and for doing a commendable job to make this event a grand success.

I wish that this conference would enrich my knowledge and provide an exceedingly excellent experience for the delegates.

(Dr. P. CHINNADURAI)

PANIMALAR ENGINEERING COLLEGE

Jaisakthi Educational Trust, An Autonomous Institution & Affiliated to Anna University

MESSAGE

Dr. C. SAKTHI KUMAR, M.E., Ph.D.,

PATRON

I extend a hearty welcome to all the delegates participating in the 8th International Conference on Intelligent Computing (IConIC 2K25) organized by **PECTEAM** on the 21st and 22nd of March 2025.

I congratulate the organizing committee for their rarity and sincerity of purpose in meticulously crafting the conference theme, and plenary sessions and bringing delegates from various organizations.

I am extremely confident that **PECTEAM 2K25** would provide a common scientific forum of discussion for the scientists, researchers, engineers, and industry experts to exchange ideas and outcomes of their research, culminating in scientific discoveries in specific areas of interest.

I extend my sincere thanks to all the keynote speakers, plenary speakers, and fellow researchers who will be for sharing their research knowledge and experience with all of us at this prestigious conference.

I wish the conference a thumping success and look forward to engaging and enriching sessions ahead and the emergence of technology shifts of this decade.

(Dr. C. SAKTHI KUMAR)

PANIMALAR ENGINEERING COLLEGE

Jaisakthi Educational Trust, An Autonomous Institution & Affiliated to Anna University

MESSAGE

Dr. K. MANI, M.E., Ph.D.,

CO-PATRON

I am extremely happy and honored to invite all the delegates to the 8th International Conference on Intelligent Computing (IConIC 2K25) on the 21st and 22nd March, 2025 being organized by **PECTEAM** in Panimalar Engineering College.

PECTEAM is a Conglomerate of eminent scientists and engineers from various fields of engineering who would be showcasing their talents and sharing their research outcomes. This conference would serve as a source finder for innovative research and a common platform for deliberations on emerging technology.

I am confident that all participants will carry pleasant memories of this event. I wish that the conference would be a grand success and a source of inspiration for aspiring researchers and entrepreneurs.

(Dr. K. MANI)

PANIMALAR ENGINEERING COLLEGE

Jaisakthi Educational Trust, An Autonomous Institution & Affiliated to Anna University

MESSAGE

Dr. S. MALATHI, M.E., Ph.D.,

CONVENER

On behalf of Panimalar Engineering College and PECTEAM 2K25, I extend a warm welcome to all delegates to the 8th International Conference on Intelligent Computing (IConIC 2K25) on 21st and 22nd March, 2025.

I am enthralled by the tremendous response to our invitation from the authors of research papers in various sectors of engineering and management. It is heartening to note that more than 400 peer-reviewed papers will be presented by the delegates.

PECTEAM 2K25 is aimed at bringing together researchers, scientists, industry leaders, and managers from various parts of India and abroad to meet and share ideas and stimulate discussions on the existing and emerging technologies in engineering research and management.

I am thankful to the Management of Panimalar Engineering College for all their support and encouragement without which this eventful conference would not have materialized.

I wish the conference a grand success and would extend my sincere and heartfelt appreciation to all the members of the organizing committee who have contributed to the success in various capacities.

(Dr. S. MALATHI)

PANIMALAR ENGINEERING COLLEGE

Jaisakthi Educational Trust, An Autonomous Institution & Affiliated to Anna University

MESSAGE

Mrs. S. VIMALA, M.Tech., (Ph.D)

CO-CONVENER

It is my privilege and honor to welcome all the delegates to the 8th International Conference on Intelligent Computing (IConIC 2K25) organized by **PECTEAM** on the 21st and 22nd of March 2025. The aim of the conference is to bring together researchers, scientists, engineers, and practitioners to exchange and share their experiences, new ideas, and research results about all aspects of tracks.

I wish **PECTEAM** a grand success and for all the enthusiasts to participate in this conference which can give immense exposure and global opportunities to all.

(S. VIMALA)

PANIMALAR ENGINEERING COLLEGE

Jaisakthi Educational Trust, An Autonomous Institution & Affiliated to Anna University

MESSAGE

Mr. STALIN RAJKUMAR
VICE PRESIDENT,
DELIVERY HEAD, RETAIL AND CPG – TECH MAHINDRA

I understand that the 8th INTERNATIONAL CONFERENCE PECTEAM2K25 is a platform for development of technologies in all Technical and Management domains with the focus on paper presentations which will finally make it to some national and international conferences.

This is a great initiative from Panimalar Engineering College, Chennai since there is an explosion of new technologies today which is transforming business world. In my opinion the significance of any technology is not in how it transforms business but more in how it impacts human life. And I hope that this conference will facilitate innovation, collaboration and convergence of ideas and minds to unearth such breakthrough solutions for the betterment of huma life. Wishing the students, researchers, industry bodies and all participating members the very best in this conference! My best wishes to the Panimalar college team!

Warm Regards,

(MR. STALIN RAJKUMAR)

PANIMALAR ENGINEERING COLLEGE

Jaisakthi Educational Trust, An Autonomous Institution & Affiliated to Anna University

MESSAGE

Dr. MANEESHA GUPTA

SCIENTIST - E, SPACE APPLICATIONS CENTRE, ISRO, AHMEDABAD

It is my distinct honour to extend warm greetings to the PECTEAM-2K25 International Conference. This two-day event on advanced technologies in technical and management domains serves as a vital platform for innovation. As we witness rapid technological advancements and shifting paradigms, the “Phoenixes” metaphor aptly symbolizes our ability to rise, adapt, and turn challenges into opportunities for growth.

I am confident this conference will foster the exchange of knowledge, ideas, and best practices, encouraging robust discussions, collaborations, and intellectual curiosity. The insights shared here will shape the future of engineering and management, driving innovation and sustainable development. Breakthroughs in artificial intelligence, renewable energy, advanced materials, and sustainable infrastructure are transforming industries and addressing global challenges. The space industry, too, demands advanced research and engineering solutions. In management, agile methodologies, data-driven decision-making, and ethical leadership are reshaping business landscapes.

With over 500 scientific papers and keynote updates, this conference demonstrates a strong commitment to cutting-edge research. Bringing together business leaders, researchers, and professionals, it will catalyze vital collaborations and impactful developments in next-generation computing. Let’s explore these emerging trends and their implications, striving to harness technology and management for a better world.

I applaud the organizers, delegates, and participants for their dedication in assembling this distinguished gathering of experts and professionals.

Warm Regards,

Maneesha Gupta

MESSAGE

Dr. JOE RYAN

SCHOOL OF INFORMATION
SCHOOL OF INFORMATION AND PHYSICAL SCIENCES,
COLLEGE OF ENGINEERING, SCIENCE AND ENVIRONMENT,
UNIVERSITY OF NEWCASTLE, CALLAGHAN, N.S.W. 2308.,

THE UNIVERSITY OF NEWCASTLE AUSTRALIA

I am writing to express my enthusiasm for the upcoming 8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management (PECTEAM 2K25), scheduled for March 21 & 22, 2025, at the esteemed Panimalar Engineering College in Chennai, India. The dedication and effort demonstrated by the organizing committee in consistently hosting the PECTEAM conference series deserve commendation. Despite challenges, this team has effectively provided a valuable platform for knowledge exchange among experts from academia, industry, and government sectors.

As we anticipate the event, I am excited about the opportunity to emphasize the importance of interdisciplinary collaboration. The fields of Computer Science, Electrical, Electronics, Mechanical, Civil and Communication Engineering, Business Systems, Artificial Intelligence, Data Science, and Machine Learning are distinct yet interconnected, playing pivotal roles in shaping our future.

The rapidly evolving landscape of engineering and management underscores the importance of events like PECTEAM in facilitating discussions and exploring innovative methodologies. Such conferences serve as catalysts for discovering new trends and ideas. I am confident that PECTEAM 2K25 will be a resounding success, fostering meaningful interactions and inspiring collaborations.

Warm Regards,

(Mr. JOE RYAN)

ADVISORY BOARD

Dr. L. Jaba Sheela
M.E, Ph.D.,
Professor & Head-CSE

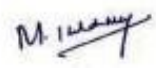
Dear Delegates,

PECTEAM 2K25 promises to be an exciting and insightful event, bringing together experts and professionals with the most brilliant minds in the field, from all around the world to discuss the latest trends and innovations in the various fields of Engineering and technology. This conference gives everyone an opportunity to innovate, find new ways of working, and adapt to changing circumstances.

Our research and innovation have the power to shape the future and improve the lives of people worldwide and it is essential to remember that our work as engineers has far-reaching consequences. I encourage you all to make the most of this conference, engage in the discussions, and take advantage of the opportunity to network with other professionals. Together, we can build a brighter future for our field and for the world.

(Dr. L. Jaba Sheela

Dear Delegates,



It's my immense pleasure to be a great part in 8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management (PECTEAM) -IConIC 2K25 on the 21st & 22nd March 2025 by Panimalar Engineering College. Several reports, congressional proposals, and administrative initiatives, all point to the need to invest in new knowledge creation and to develop a skilled workforce and infrastructure, necessary to support this innovation.

This Conference will provide an opportunity to quench the thirst for knowledge. The purpose of this conference is to bring together researchers, experts from various industries, academicians, and other interested organizations to meet, and exchange information, ideas, and various developments in the field of Information and Technology.

I wish the organizers great success in their endeavor.

Dr. M. Helda Mercy

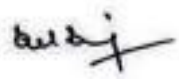
Dear Delegates,

It gives me immense pleasure to know that Panimalar Engineering College, Chennai is organizing for Phoenixes on Emerging Current Trends in Engineering and Management (PECTEAM)-IConIC 2K25. I am sure that this conference will provide a forum for national and international students, academicians, researchers, and industrialists to interact and involve in Research and Innovation. Such academic events benefit the students, teachers, and researchers immensely and widen the horizons of their knowledge and work experience in the field of Data Management, Analytics, and Innovation.

I sincerely appreciate the humble efforts of the Institute in providing a platform for students, academicians, researchers, and industrialists to share their ideas and research outcome through the forum of this Conference. I give my best wishes to all delegates and the organizing committee to make this event a grand success.

(Dr. S. RajaKumar)



Dear Delegates,

It is a great pleasure for me that our college is conducting the 8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management (PECTEAM)-IConIC 2K25 on 21st and 22nd March, 2025. The conference is a platform for information exchange between the end user, and the research communities. The purpose of this conference is to bring together researchers, experts from various industries, academicians, and other organizations to exchange information, ideas, and developments in the field of Electrical Engineering.

I hope this conference PECTEAM 2K25 will be enjoyable, memorable, and productive for participants, and looking forward to technological innovations.

Dear Delegates,

I am delighted to be part of the "8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management" (PECTEAM) -IConIC 2K25 to be held on March 21st and 22nd, 2025 by Panimalar Engineering College. The theme for the Conference is to provide a spectrum of opportunities, overcoming hardships and challenges, breakthrough innovation & creativity, leading change, and re-engagement. Also, this conference is intended to provide a forum for research scientists, engineers, and practitioners to present their latest research findings, ideas, and applications.

I cordially appreciate the paper presenters and participants with great ideas. I express my heartfelt thanks to our respectable management and the Organizing Committee for their sincere efforts. May this conference be characterized by fruitful thought-provoking discussions, which will lead to the betterment of our society. Best wishes for its grand success.

(Dr. B. Anni Princy)

Dear Delegates,

I am very much privileged to be a part of "8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management" (PECTEAM) - IConIC 2K25 by Panimalar Engineering College. It is an attempt to focus the attention of all concerned professionals to discuss at length concerned with the Emerging trends in Engineering and Management to seek solutions wherever possible and identify areas where further researches are needed. Invited contributions from experts on various topics are presented in the proceedings.

We look forward to an exciting and insightful presentations, discussions, and sharing of technical ideas with colleagues from around the world. On behalf of the Department of Computer Science and Business Systems, I take this opportunity to record my heartfelt appreciation and gratitude to all the authors, delegates, conference chairman, and all other participants.

Professor & Head - MECH

Dear delegates,

On behalf of the Department of Mechanical Engineering and the Advisory committee, I am delighted that Panimalar Engineering College will host the 8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management (PECTEAM) - IConIC 2K25 on March 21st and 22nd, 2025, for the benefit of academicians and research scholars, as well as to generate innovative ideas, products, and knowledge of the most recent trends in mechanical engineering.

My heartfelt wishes for the success of the International Conference PECTEAM 2K25. I greet all the delegates, speakers, and conveners. This conference aims to improve knowledge and abilities across a range of disciplines.

Dear Delegates,

I am extremely happy to share that our college is taking strenuous efforts to organize the 8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management(PECTEAM)-IConIC 2K25 from 21/3/2025 to 22/3/2025 by Panimalar Engineering College .There has been a tremendous amount of discussion over the past few years regarding the importance of Control Instrumentation, Communication and Computational Technologies, and Innovation. Several reports, Congressional proposals, and administrative initiatives, all point to the need to invest in new knowledge creation and develop a skilled workforce and infrastructure; necessary to support this innovation. The International Conference will provide an opportunity to quench the thirst for Knowledge.

The sessions by eminent personalities will bring out the significance of the topic in the present scenario. I am sure that the Conference will be very informative for aspiring young Undergraduates, Post-graduates, Research scholars, and Staff members. I congratulate the convenors and organizers for their sincere initiative. My best wishes for the fruitful deliberations at this International Conference.

Dear Delegates,

I am very much glad to be a part of the 8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management (PECTEAM)-IConIC 2K25 on 21st and 22nd March 2025.It will underpin the need for collaboration and cooperation of individuals from a wide range of professional background.

The aim of the conference is to bring together the leading academic scientists, researchers, and research scholars to exchange, as well as share their experiences and research findings about all aspects of Engineering and Technology. It also provides the premier interdisciplinary forum for researchers, practitioners, and educators to present and discuss the most recent innovations, trends and concerns, practical challenges encountered, and the solution adopted in various fields of Engineering and Technology.

(Dr. M. Mageswari)

Dear Delegates,

We, the Panimalar Engineering College is organizing the 8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management (PECTEAM)-IConIC 2K25 on the 21st and 22nd of March, 2025. I feel most honored and privileged to convey this message. The scope of the PECTEAM is to provide an International forum for researchers, academicians, students, developers, and practitioners from the industry for the exchange of ideas and knowledge.

I am sure that the conference would enjoy great success in its intended purpose and wish all the delegates and participants a very purposeful two days of meaningful deliberations. My best wishes for the fruitful deliberations at this International Conference.

Dr. N. Venkatesawaran

DEAN / H&S

Dear Delegates,

The 8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management (PECTEAM)-IConIC 2K25 on 21st and 22nd March ,2025 is a memorable event, adding a feather to the cap towards the ever-beckoning horizon of excellence in the chronology of Panimalar Engineering College.

The main objective of PECTEAM-2K25 is to confluence the researchers, scientists, and experts in institutions for sharing adroit and cognizant of the recent developments in Engineering, Technology and Management Studies to invent, innovate, improve, design, build and thereby, to develop novel structures, tools, components, and materials.

I cordially accolade the paper presenters and participants with Multi-lingual and cultural backgrounds to be endowed with copious knowledge. In addition, I would like to eulogize the committee members for their diligence and commitment in ensuring the grand success of the conference.

(Dr. R. Manmohan)

Dear Delegates,

Its a great pleasure to be a part of this 8th International Conference for Phoenixes on Emerging Current Trends in Engineering and Management (PECTEAM) -PECMACT 2K25 on the 21st & 22nd March 2025 by Panimalar Engineering College. This event promises to be a remarkable opportunity for us to expand our horizons, collaborate with leading experts, and contribute to the advancement of knowledge in our respective fields.

Our aim is to foster interdisciplinary dialogue, encourage networking, and inspire new avenues of research and collaboration. This conference offers an excellent platform for networking and forging partnerships with colleagues from diverse backgrounds. Let us come together to celebrate the spirit of inquiry, innovation, and collaboration and let your academic journey soar to new heights.

DR.T.TAMILSELVI
Prof.V.JEYARAMYA
Prof.M.MEGALA
Prof.J.ANITHA
MR.M.VETRISELVAN
MR.J.STEPHAN
MS.M.POVANESWARI

PLENARY SPEAKERS

Mr. NAGARAJ MANOHARAN
Associate Manager
Accenture, Chennai.

Dr. DHIVYA
Analyst II
Data Analytics Team
Dun and Bradstreet, Chennai.

Mr. JAGADISH
Technical Program Manager
Microsoft Company, Hyderabad.

Mr. SURENDHAR .SV
Senior Cyber Security Researcher
LTI MindTree Limited, Chennai.

Mr. ARUN PRASAD
Consultant Architect
Soprasteria, Chennai.

Mr. K. RAJA
Cloud Architect
Soprasteria, Chennai.

Ms. SUTAPA DUTTA
Senior Manager, Technical Operations
Nokia

Ms. KALPATHY G LAKSHMI VIPIN
Global Head – Ethics and Business Integrity
Redington India Ltd

Ms. YADHUVARSHINI R
Community Builder
Guvi Geek Network

Mrs. SANGEETHA JOTHIRAMAN
Project Manager
CTS, Chennai.

Mr. T. J. ASHWIN KUMAR
Cyber Security Lead
TCS, Chennai

Mr. ARUN T
Junior Web Developer
Guvi Geek Network

Ms. PRAVEENA G
Senior Developer
Cognizant Technology.

Mr. MOHAMMED WAJID ALI
Testing Director
TCS

Mr. MOHAMMED WASIM
Team Leader (Senior Technical Lead)
HCL

Mrs. RAJALAKSHMI SURESH
Application Architect
IBM, Chennai

Mrs. PARIMALA PRIYA GAJENDRAMANI
Senior Delivery Manager
IBM, Chennai

Mrs. V. JEYA GEETHA
Assistant Professor / CSE
St. Joseph University

Mr. PRADEEP
Senior Software Engineer
Viasat

Ms. PANIMALAR S
Lead Infra Engineer
Datasirpi Private Limited

Dr. B. CHITRA
Senior Data Analyst
Accenture, Chennai.

Ms. HAREESHMA BALAJI KUMAR
Senior Software Engineer
Siemens, Bangalore

Mr. VIJAY ARAVINTHAN J
Program Analyst
Cognizant Technology Solutions Corporation (CTS)

Mr. SHEIK MOHAMMED ARSATH
R & D Engineer
Bonfiglioli Transmission Ltd.

Ms. SAI PRABHA
System Engineer
TCS, Chennai.

PLENARY SPEAKERS

Dr. B. MURUGESHWARI
Professor and Head
Department of CSE
Velammal Engineering College, Chennai.

Mr. E. MAHENDRAN
Joint Director
CDAC, Chennai.

Dr. T. JAYASREE
Associate Professor
Department of ECE
Government College of Engineering, Bodinayakkanur,
Theni District, Tamilnadu, India.

Dr. M. RAJESH
Associate Professor
Department of Computer Science and Engineering
Aarupadai Veedu Institute of Technology, Chennai.

Dr. DHALIA SAM
Professor
Department of IT
MGR University, Chennai.

Dr. A. ALICE NITHYA
Professor
SRM Institute of Science and Technology
Kattankulathur.

Dr. S. ILAVARASAN
Associate Professor
Department of Information Technology
Saveetha Engineering College, Chennai.

Dr. JOE RYAN, Ph.D.
School of Information and Physical Sciences
College of Engineering
University of Newcastle, Australia.

Mr. A. JEYABAL
Plant Head
SPU (Foundry Division)
Ashok Leyland, Chennai.

Dr. A. PALANI
Professor
School of Management Studies
Sathyabama Institute of Science and Technology,
Chennai.

Dr. M. HEMALATHA
ASP
RMK.

Dr. S. SOUNDARARAJAN
Vice Principal and Professor
Department of CSE
Velammal Institute of Technology, Chennai.

Dr. H. UMMA HABIBA
Professor
Department of ECE
Bharath Institute of Higher Education and Research,
Tambaram, Chennai - 600 073.

Dr. I. POONGUZHALI
Associate Professor
Department of ECE
Panimalar Engineering College.

Dr. GEETHA C
Associate Professor
Sathyabama Institute of Science and Technology.

Mrs. MALVIKA KUMAR
Director of Operations
Infoziant IT Solutions.

Dr. F. ANTONY XAVIER BRONSON
Associate Professor
Department of CSE
Dr. M. G. R. Educational and Research Institute,
Maduravoyal, Chennai - 95.

Dr. ELANTHERAIYAN P
Associate Professor
Department of MBA
Vel Tech Rangarajan R&D Institute of Science and
Technology, Chennai.

INDEX

S.No	PAPER ID	TITLE OF THE PAPER & NAME OF THE AUTHORS	Page.No
1	41	Ai Driven Fashion Design System	1045
2	72	Iot-Enabled Adaptive Energy Management For Electric Vehicles Using Real-Time Optimization	1052
3	76	The Infant Cry Classifiation Using Mel Spectrograms And Deep Learning Based Neonet Classifier	1058
4	77	Design And Analysis Of Dual Band RF Harvesting Microstrip Patch Antenna For Autonomous Wireless Sensor Network Applications	1072
5	81	Advanced Algae Cultivation Techniques For Sustainable Biofuel Production Using Iot: A Survey	1083
6	82	Efficient P-Wave And S-Wave Detection Using MODWT And STA/LTA Ratios For Earthquake Early Warning Systems	1098
7	110	An Ai Powered Avatar Emulation For Conversation-A Realistic Interview	1111
8	116	Assessing The Impact Of Iot On Smart City Development In India: Challenges & Opportunities	1127
9	128	An Intelligent Computer Vision System For The Detection And Classification Of Plant Diseases	1135
10	131	Optimizing Fake News Detection With Multi-Feature Extraction And Machine Learning Ensemble Methods	1143
11	141	Ai Integrated Fire Fighting Rover	1155
12	146	Audio-Guided Smart Spectacles: Enabling Independence For The Visually Impaired	1158
13	152	Design And Development Of An Enhanced Detection System For Track And Rescue Of Enmeshed Victims Under Wreckage	1169
14	164	Automated Agricultural Field Analysis And Monitoring System (AAFAMS) Technology	1179
15	173	Detect Fake News Using Machine Learning Techniques	1191
16	175	Lung Cancer Detection Using Deep Learning	1199
17	179	Smart Fashion: How AI And Mobile Cameras Are Redefining Outfit Selection	1206
18	180	AI-Driven Forensic Analysis: Enhancing Crime Scene Reconstruction With Machine Learning	1216
19	185	Optimizing HER2 Scoring In Breast Cancer: AI Integration Of SSL, XAI, FL And IHC-FISH Data	1224
20	209	Myers-Briggs Type Indicator (Mbti) Student Empower App – Course Selection Based On Personality Types	1231
21	212	Aquatic Ecology: Harnessing Water Quality In Fisheries Management	1239
22	221	Fresh Sense : Revolutionizing Produce Quality Monitoring With Autonomous Drone Technology	1244
23	224	Undersampled Mri Reconstruction Using Scan-Specific Self-Supervised Bayesian Deep Non-Linear Inversion	1255
24	230	Virtual Encyclopedia Using Argumented Reality	1262

25	236	Automated Sound Captioning Using Conformer Model	1269
26	244	Innovative Structural Health Monitoring System with Fog-Cloud Synergy	1287
27	262	A Wide Assistance on Location Crises-Based Web Application	1294
28	271	Medi Plant AI: Deep Learning-Powered Web Application For Medicinal Plant Detection And Chatbot-Assisted Recommendations.	1299
29	290	Alzheimer's Detection Using Deep Learning	1309
30	298	Ai-Powered Home Fire Alarm And Detection	1314
31	302	Smart Ambulance Dispatch System	1323
32	312	ADHD Detection In ASD Children Using Handwriting Analysis	1332
33	318	Improving Navigation For Visually Impaired Individuals: Biped Constraints, Landmarks And Assistive Systems	1339
34	324	Community-Based Mental Health Support App	1346
35	328	Self - Attention Based Personality Prediction	1356
36	329	Legallift: AI-Powered Legal Assistance For Affordable And Efficient Justice	1366
37	336	Quantum Computing For Financial Modelling	1372
38	339	*Integration Of AI Into Microwave Imaging Device For Early Detection Of Breast Cancer*	1385
39	340	An AI-Powered Nutrition and Wellness Recommendation System for Expecting Mothers Based on Fetal Development	1402
40	341	Predicting $PM_{2.5}$ And PM_{10} Using Machine Learning Models Particularly In Urban Cities Like Chennai, India.	1410
41	345	*Capacitating E-Waste Management In The Real World For Sustainable Development*	1422
42	350	Quantum Computing Drug Discovery Approaches Using Machine Learning	1432
43	362	Agri Sense: Pre-Emptive Disease Detection And Forecasting Platform	1439
44	370	An Ai-Powered Chatbot For Real-Time Soil Quality Analysis	1448
45	375	Enhancing Cybersecurity: Detecting Keyloggers Through Signature Algorithms	1458
46	378	Dynamic Face Recognition Leveraging Computer Vision Techniques	1464
47	379	Ai & Ar-Enhanced Smart Glasses: A Real-Time Assistive Solution For Color Blindness	1472
48	388	Smart Farming Made Accessible: A Budget-Friendly Ai-Powered Automation Solution	1487
49	394	Blood Print: A Deep Learning Model for Predicting Blood Group	1493
50	400	Edge-Optimized Tamil OCR Via Dynamic Fusion-Enhanced CNN Architecture	1499
51	401	Advancing Iov: A Survey On AI, Blockchain, And Edge Computing For Intelligent Vehicular Networks	1508
52	405	Smart Vehicle Compliance&Fake Number Plate Detection	1519
53	414	Unlocking Identity: Fingerprint-Based Gender Classification Using IVMD-Attention Based Efficientnet Model	1525
54	419	Sky Guardian's: The Game-Changer In Earthquake Survival Strategies	1531

55	423	Hand Gesture Recognition And Visual Feedback For Inclusive Communication In Deaf And Mute Communities	1539
56	424	Ai-Driven Cost-Effective Personalized Medicine For Optimal Treatment And Availability	1549
57	425	Mentor Connect: AI-Driven Career Mentorship Platform For Personalized Growth And Skill Development	1557
58	427	Next-Generation Wireless Intelligent Connectivity: Advancing From 5G Convergence To 6G Realization	1565
59	433	AI-Driven Insider Threat Detection: Leveraging Augmented Reality For Next-Gen Security	1575
60	435	Biomedical Computing Meets Cybersecurity: A Hybrid AI Approach To Protecting Health Records	1585
61	440	Watchmind:The Interactive AI Companion For Next-Generation Personalized Learning And Intelligent Monitoring	1597
62	441	Early Identification Of Hearing And Vision Problem Using Mobile Gaming App	1606
63	447	A Reinforcement Learning-Based Gamified System For Reintegration Of Hikikomori	1615
64	450	Predictive Modeling For Chronic Heart Failure Readmission Risk Using Artificial Intelligence	1622
65	455	Donation And Food Donation Management System	1628
66	456	Enhancing Local News Web App With Advanced Features	1633
67	457	Efficient Multi-Authority Attribute-Based Signcryption	1643
68	458	Virtual Ai Health Assistant: A Novel Framework For Equitable Healthcare Access In Underserved Communities Using Federated Learning And Generative Ai	1656
69	471	Ai-Powered Dermatological Disease Prediction Using Deep Learning	1667
70	484	Robust Sign Language Recognition Using Convolutional Neural Networks (Cnn)	1676
71	490	Rapid Response Network (A+Sos) Using Artificial Intelligence	1683
72	492	Automated MRI-Based Detection Of ADEM Using Deep Learning Models	1690
73	493	Evaluating The Credibility Of Influencer Advertisements Using Data Analytics	1703
74	496	PINN-Enhanced MOSFET Modeling: A Hybrid Framework For Scalable PSP Parameter Extraction	1710
75	507	Transfer Learning - Based Hybrid Approach For Accurate Prediction Of Lung Diseases	1723
76	510	Predictive Analysis For Ipl Cricket Score Using Machine Learning	1732
77	517	Embedding LSTM And Online Gradient Descent For Stock Market Analysis And Customized Recommendation Systems	1739
78	527	Ai Powered Fitness Coach System Using Machine Learning For Personalized Workout	1744
79	534	*Automated Road Damage Detection And Classification Using Resnet Blended Five Dense Layered Deep Fully Connected Neural Network Integrated With Geographical Information Systems And Satellite Imagery*	1753
80	535	Aquashield:Interactive Real Time Flood Risk Mapping and Alerts	1759
81	537	Customer Churn Prediction	1768

82	539	Autonomous AI-Driven Armored Combat Vehicle For Intelligent Target Recognition And Engagement	1776
83	540	Financial Fraud Detection System	1789
84	541	Enhancing Human And Animal Detection In Challenging Environments Using Sonar And Multi- Sensor Technology	1798
85	542	Revolutionizing E-Commerce With AI: The Future Of Intelligent Image Generation	1806
86	551	Unmasking Deepfakes: Advanced Detection Techniques For Digital Integrity	1819
87	553	AI-Powered Life Optimization: A Smart, Adaptive, And Personalized Recommendation System	1830
88	554	*Fake News Detection With Explainable Ai: Enhancing Trust In Media And Digital Information*	1854
89	556	Urbanisation Planning For Sustainability Using Ai	1862
90	557	Ai-Powered Dermatology Assistant: Facial Skin Condition Detection Using Deep Learning	1870
91	561	Ai Based Navigation For Visually Impaired	1881
92	562	AssistAI: An AI-Powered Care Assistant For Elderly And Disabled Individuals	1889
93	564	Ai Powered Smart Waste Segregation System Through Computer Vision	1897
94	565	Digital Twin: Bridging The Physical And Virtual For Intelligent Systems	1913
95	566	Electric Vehicles And Their Environmental Impact: A Lifecycle Assessment	1922
96	572	AI - Driven Exoskeletons: Enabling Movement For Paralyzed Individuals Through Brain-Signal Detection	1928
97	573	An Advanced Surveillance Framework For Womensafety Analytics:Real-Timedetection, Threat Prevention,And Law Enforcement Integration	1935
98	574	Deep Learning-Based Emotion-Driven Music Recommendation System	1948
99	576	Pioneering Breast Cancer Detection Via Fingerprint Analysis	1962
100	577	Design And Performance Analysis Of Multiply And Accumulate (MAC) Unit For Machine Learning Acceleration	1070
101	578	Tri-Genx: The Intelligent Blend Of Wind, Solar & Hydro	1983
102	583	Vidopti-Compresso: An AI-Driven Evolutionary Optimization Technique For Video Compression	1994
103	587	Ai-Based Thermo Steam Power Generation	2004
104	588	Mitigating The Environmental Impact Of Plastic Degradation In Marine Ecosystem	2014
105	593	Injury Prediction And Prevention For Cricket Players Using AI	2032
106	595	Predictive Modeling Of Lung Cancer Using Machine Learning: Towards Early And Accurate Diagnosis	2042
107	598	Digital Twin Technology In Telehealth : The Next Frontier	2054
108	600	Ai – Translator For Inclusive Communication	2064
109	605	Passnest: Secure And Serene	2074

110	607	Soilxpert: Smart Monitoring System For Sustainable Agriculture	2084
111	608	Blockchain-Powered Bank Records Storage System	2091
112	610	Proactive Toxic Gas Detection System For Mining Safety Enhancement	2097
113	621	Blockchain-Powered Mobile Banking: Advancing Security And Fraud Prevention	2105
114	623	Classification Of Oral Cancer From White Light Images Using A Hybrid Machine Learning Algorithm For Enhanced Accuracy	2110
115	627	Smart Attendance Monitoring System Using Face Recognition For People With Disabilities (Pwds).	2119
116	628	Macros And Nutritional Value Tracker Web App Using Python And Mongodb	2132
117	633	Unlock Your Movement : Ar – Driven Orthopedics	2142
118	642	Leveraging Convolutional Neural Network For Detection Of Sugar Cane Leaf Disease	2151
119	643	Context-Aware Named Entity Recognition For Legal Documents – A Hybrid Approach Using Rule-Based And Deep Learning Model	2159
120	645	Ai-Based Low-Resolution Cctv Image Enhancement For Criminal Identification Using Esrgan, Scrfd, And Arcface Models	2175
121	647	Exchange Ease: A Trust-Based Digital Barter Marketplace	2187
122	651	AI-Based Cryptanalysis Using Reinforcement Learning For Identifying Vulnerabilities	2200
123	652	Hybrid Federated Blockchain For Secure And Scalable Iot Vehicular Networks In Edge Cloud Computing	2212
124	655	Smart Blood Donation And Emergency Request System	2231
125	657	Eyes In The Abyss: Ai-Powered Drones Effect On Marine Conservation	2240
126	658	Modern IOT Based Blind Stick For Visually Impaired To Identify Obstacle Voice Detection	2246
127	660	High Accuracy In Plant Disease Detection Using Transfer Learning Techniques	2254
128	661	Performance Analysis Of The Microstrip Antenna	2260
129	662	Enhancing Rolljam Attacks With AI:A Next-Generation Implementation And Counter Measure Research	2275
130	665	Smart Fit : Ai-Driven Virutal Dress Try-On For Online Shopping Using Cnns, Gans, And 3d Cloth Simulation	2290
131	666	Real-Time Sign Language Conversion Into Text And Speech	2304
132	667	Integration Of Raspberry Pi 4 And Yolo V8 For Precision Laser-Guided Target Detection And Tracking In Loitering Applications	2312
133	668	Language Detection And Translation From Image Using Machine Learning	2322
134	669	Sybil-Integrated YOLO Model For Deep Learning-Based Lung Cancer Prediction	2329
135	671	A Generative Approach To Enhance Keystroke Dynamics Security: Injection Attack Detection And User Authentication	2338
136	673	Tracknseat: Smart Bus Seat Vacancy Detection & Arrival Alerts	2344
137	674	AI-Based Crisis Detection And Prediction Using Twitter Data	2354

		And Geospatial Analysis	
138	676	64-Bit Design Using Vedic Mathematics In Verilog	2368
139	682	Automated Billing Shopping Cart Using Arduino Uno	2378
140	684	AI-Driven Threat Intelligence: Enhancing Dark Web Monitoring For Stolen User Data	2386
141	685	AI-Enabled Threat Direction: Intelligent Wearable For Real-Time Child Safety Monitoring	2398
142	687	Review Of Machine Learning Technique Based Prediction Model For Phishing Websites Detection	2410
143	690	Ai Healthscan: Multi-Disease Prediction Using Machine Learning	2415
144	691	A Comparative Analysis Of Machine Learning And Deep Learning Approaches For Fake News Identification	2427
145	692	A Secure Blockchain-Based Voting System Using Sha-256 Pin Authentication	2438
146	694	Spamvision: AI-Driven OCR And NLP For Image Spam Filtering	2447
147	695	Sentiment Analysis Using Natural Language Processing (Nlp) For Online Trading	2454
148	698	Hallucination Detector In Chatbot	2464
149	702	Unsupervised Approaches For Traffic Sign Image Segmentationin Autonomous Driving	2470
150	704	Delivery Via Autonomous Drone	2482
151	705	Automated E-Commerce Price Comparison System Using VGG And SVM	2489
152	706	Parkinson Disease Detection Using Machine Learning	2500
153	707	Deep Learning Based Model For Fake Product Review Detection	2507
154	712	AI-Powered Solutions For Food Redistribution Real-Time Optimization And Predictive Analysis To Combat Hunger	2513
155	714	Future Prospects Of AI-Driven Competitive Intelligence In E-Commerce	2519
156	718	Blink And Listen: An Audio -Enhanced Control System Using Mems And Emg Sensors	2530
157	727	Dual-Battery Electric Vehicle: Enhancing Efficiency And Performance Through Battery Swapping	2555
158	728	Configurable Low Power High Speed ImageSensor: Data Sampling Through Adaptive Scaling	2562
159	731	Wireless Charging Roads For Electric Vehicles	2571
160	734	Car Parking Reservation And Online Payment	2579
161	735	Enhancing Agricultural Monitoring Using Magnetic Induction-Based Wireless Underground Sensor Networks	2588
162	738	Product Recommendation System	2595
163	744	Argumen Chatbot Using Unity	2603
164	748	Self-Sustaining Wristwatch For Women's Safety: Gps-Activation Sensors And Energy Harvesting Technology	2612
165	751	Ember Safe Fire Prevention Powered By Sun	2628
166	752	Ai-Driven Animal Detection And Alert System For Road Vehicles	2626
167	759	AI Health Nexus: A Unified AI, RAG, And Iot-Based Smart Healthcare System	2632

168	760	Flow Over An Infinitely Accelerating Vertical Plate With Homogeneous Heat And Mass Flux In A Viscous Fluid Medium	2643
169	761	Swarm Intelligence For Autonomous Cybersecurity: A Decentralized Framework For Threat Detection And Response	2652
170	762	Infant Cry Recognition System Using Arduino And Frequency- Selective Acoustic Detection	2658
171	763	Quantum-Optimized AI Swarm Robotics For Autonomous Nanoscopic Oil Residue Deconstruction In Cryogenic Fluidic Environments	2664
172	767	Unlocking The Quantum Realm: A Journey Through Qubits And Algorithms	2670
173	770	A Scalable Framework For Explainable Spam Detection: Integrating SHAP, LIME, And User Feedback.	2678
174	771	IOT & AI-Based Autonomous Pet Health Monitoring And Environmental Adaptation.	2684
175	772	Enhancing Online Payment Security With Xgboost Algorithm For Real-Time Fraud Detection	2690
176	773	Machine Learning Approach For Fault Detection In Regenerative Braking System	2699
177	774	Enhancing Cyberbullying Detection On Social Media: Leveraging Linear Regression	2714
178	776	Smart Drip, Smarter Crops: AI-Powered Precision Irrigation For Water Efficiency	2724
179	779	Enhancing Medical Imaging With AI Using CNN And U-Net: A Portable PDA-Based System For Smarter Diagnostics - Tele-Radiology	2733
180	780	Robust Video Steganography Using Hybrid Crypto-Stego Techniques	2742
181	782	Predictive Modelling For Network Threat Detection Using Artificial Intelligence Techniques	2751
182	784	An Innovative Tool For Ddos Detection And Mitigation In Cybersecurity	2758
183	786	Exploring The World Of Virtual Assistants	2769
184	787	Accessai: Smart Inclusion Detection	2775
185	788	Therapeutic Environment For Personalized Anxiety Disorder Treatment	2781
186	790	Route Optimization For Delivery Services Using Convolutional Neural Networks	2788
187	791	AI -Driven Soil Nutrient Detection And Fertilization Optimization	2798
188	792	A Novel Tree-Based Approach To Mine Sequential Patterns	2807
189	793	A Novel Estimation Of Age And Gender By Face Recognition Using CNN With VIT	2816
190	795	A Scalable Machine Learning Model For Dengue Outbreak Prediction And Risk Assessment	2825
191	800	Text Summarization Using Nlp And Transformers	2832
192	804	Privacy-Preservation AI For Women's Safety Critical Surveillance	2839
193	805	*Automatic Height-Adjusting Bridge With Enhanced Safety Features And Solar Power Integration*	2845
194	806	Telehealth: Reducing Healthcare Costs With Mobile Solutions	2851
195	807	A Comprehensive Analysis Of Recent Developments In Chatbot Technology	2857

196	809	Exploring Optimization Approaches In Machine Learning For Solving Agricultural Challenges	2863
197	811	Ai Train Safety	2872
198	812	Live Alive: Make Life Beautiful	2876
199	822	Transforming Energy Sustainability In Small Island Nations: The Role Of Smart Grids And AI-Driven Optimization For Renewable Energy Integration And Demand Management	2883
200	826	Phygital Fit: An AI-Driven Virtual Footwear Solution Integrating Generative AI, AR And Foot Morphology Analysis For Personalized Fit	2892
201	827	Connected Home Project A Compact Based Iot-Driven Automation System	2902
202	828	Employee Stress Management System	2907
203	831	Vocal Aura: Merging Human Expression With Ai-Enhanced Voice Synthesis For Creativity	2916
204	834	Cvd Prediction And Organic Prescription	2933
205	836	3d E-Commerce Website Powered Ai	2940
206	842	Demand forecasting in e-commerce	2947
207	843	Deep Learning For Multimodal Emotion Recognition Integrating Facial Expression And Speech	2954
208	848	Road Safety With Smart Signal Technology	2961
209	849	Ai Powered Nir Imaging For Wax Detection On Fruits And Vegetables: A Handy Approach	2968
210	855	Aı Streamlined Clinical Documentation System	2980
211	856	From Linear Urbanization To Circular Solar-Powered Cities:Ecogenis	2990
212	857	Webunity: AI-Infused Synchronous Synergistic Compilation Framework For Decentralized Web Architectures	2996
213	858	"Predictive AI And GPS-Coupled Autonomous Control For Next-Gen ATP"	3002
214	859	Quantum-Enhanced Crowd Management System For Large-Scale Events: Harnessing Predictive Power For Smarter Event Management	3008
215	861	From Concrete To Canopy: Rewilding Cities for a Greener	3015
216	862	Innovative Solutions For Autonomous Systems In Dynamic Environments: Energy Harvesting, Predictive Algorithms	3021
217	863	Quantum-Enhanced Self-Learning Deepfake Detection And Prevention System	3027
218	874	Influence Of Chemical Reactions And Radiation On A Vertically Oscillating Plate	3034
219	876	Deep Manifold Learning For Pk Optimization	3049
220	880	Design And Development Of An AI-Enhanced Foldable Electric Tricycle For Smart Mobility	3055
221	881	Innovations In Electric Vehicle Powertrains: A Compareative Analysis	3062
222	882	Federated Learning In Medical Imaging: Effect Of Data Skewness And Client Participation	3068
223	883	Heartlink: Iot Smartwatch For Emergency Alerts	3076
224	884	Intelligent Surveillance System For Student Compliance Monitoring	3085
225	887	A Survey On Climate Change And Waterborne Diseases: Risk Patterns And Management Strategies	3095
226	888	*Skin Cancer Detection Using Efficientnet(Cnn)*	3101

227	889	Examining The Relationship Betweenworklife Balance And Employee Mental Health For Organizational Culture	3114
228	890	Crypto Price Forecasting & Sensor Security With AI	3122
229	894	Auraflow: Daily Emotional Wellness Tracker	3131
230	896	Enhancing Secure Authentication And Authorization In 5g Network Slicing Using 2pvc Algorithm In Blockchain	3139

Abstract--The fashion industry is changing as a result of the incorporation of machine learning (ML) and artificial intelligence (AI) technologies, which enhance creativity, automate processes, and improve efficiency. This paper presents an AI-powered method for fashion design that leverages advanced deep learning models to revolutionize traditional design workflows. The system employs Generative Adversarial Networks (GANs) to produce creative designs, machine learning algorithms for trend forecasting, and AI-powered tools for fabric pattern analysis. By incorporating intelligent automation and predictive analytics, the proposed system addresses the growing demand for personalized and sustainable fashion. Experimental results demonstrate significant improvements in design efficiency, creativity, and consumer engagement. This work underscores the possibilities of ML and AI in fostering innovation, driving sustainability, and redefining the future of fashion design. Keywords: Artificial Intelligence (AI), Machine Learning (ML), Fashion Design, Generative Adversarial Networks (GANs), Trend Forecasting, Fabric Pattern Analysis, Sustainable Fashion, Predictive Analytics, Design Automation, Personalization.

I. INTRODUCTION

The fashion industry is a vibrant, quickly changing field that depends heavily on creativity, innovation, and consumer preferences. But conventional design methods are frequently time-consuming, labour-intensive, and reliant on subjective human creativity. Since the development of machine learning (ML) and artificial intelligence (AI), new opportunities have emerged to enhance efficiency, improve accuracy, and foster innovation in fashion design.AI and ML technologies enable automation, intelligent decision-making, and insights derived from data, making them pivotal in transforming the fashion industry. Generative Adversarial Networks (GANs), one type of generative model, have shown remarkable capabilities in creating novel and aesthetically pleasing designs by learning patterns from existing datasets. Additionally, AI-driven trend forecasting tools analyze enormous volumes of data to forecast upcoming fashion trends, enabling designers and manufacturers to stay ahead in a competitive market.AI integration in fashion extends beyond trend forecasting and design. AI-powered systems are increasingly being used for fabric pattern recognition, quality control, and personalized recommendations, which enhance customer engagement and satisfaction. Furthermore, sustainability has become a critical focus in the industry, with AI and ML being leveraged to optimize resources, reduce waste, and promote eco-friendly practices.

This paper proposes an AI-driven fashion design system that combines generative models, predictive analytics, and intelligent automation to revolutionize traditional workflows. The system addresses key challenges such as the demand for personalization, the need for sustainable practices, and the increasing complexity of consumer preferences. By integrating advanced AI techniques, this research aims to redefine the future of fashion design, making it more innovative, efficient, and sustainable.The rest of the paper is organized as follows: Section II reviews the related work in AI-driven fashion systems. Section III outlines the proposed methodology, detailing the

models and techniques employed. Section IV presents the implementation and results, demonstrating the system's effectiveness. Finally, Section V concludes the paper and discusses future research directions.

II. LITERATURE SURVEY

This section reviews the latest developments and uses of machine learning (ML) and artificial intelligence (AI) in the fashion design sector, highlighting their impact on creative processes, consumer engagement, and industry efficiency.Yan et al. [1] proposed a fashion design system that uses Generative Adversarial Networks and AI that integrates generators for sketches and renderings to assist designers. The approach facilitates intelligent design processes and bridges the gap between creativity and computational design. Similarly, Jeon et al. [2] introduced FashionQ, a tool powered by AI that supports fashion design ideation by leveraging creativity support systems.
Csanák [3] discussed the general use of artificial intelligence in fashion, highlighting its potential in transforming traditional design and production workflows. Gu et al. [4] developed iDesigner, an intelligent platform for generating fashion designs using deep learning models, showcasing its utility in automating design tasks and enhancing creative output.Lyu and Lv [5] explored the integration of AI and big data in the digital transformation of the fashion industry, emphasizing trends such as personalization and predictive analytics. Mohamed et al. [6] analyzed the interplay between AI, intellectual property rights, and innovation in fashion design, highlighting legal and creative challenges.Mohiuddin Babu et al. [7] examined the influence of AI in forming the agile fashion industry, addressing its impact on supply chain optimization and real-time decision-making. Noor et al. [8] provided a thorough analysis of AI applications in the apparel industry, identifying advancements in design, marketing, and production processes.Huang et al. [9] proposed a deep learning-based method for fabric defect segmentation, showcasing AI's potential in quality control within fashion manufacturing. Han et al. [10] utilized machine learning for color trend analysis using fashion collection images, contributing to automated trend forecasting.Iqbal Hussain et al. [11] focused on woven fabric pattern recognition using deep convolutional neural networks, demonstrating significant improvements in pattern analysis and classification. Finally, Sohn et al. [12] explored consumer responses to GAN technology in fashion, providing insights into AI's influence on consumer engagement and market trends.This review underscores the diverse applications of AI and ML in fashion, spanning design automation, trend prediction, quality control, and consumer interaction. It also highlights the opportunities and challenges in adopting these technologies for innovative and sustainable fashion practices.

III. PROPOSED METHODOLOGY

This section outlines the tactic adopted to develop the AI-driven fashion design system. The approach leverages state-of-the-art artificial intelligence and machine learning models to automate and enhance various stages of the fashion design process, from conceptualization to trend analysis.

Data Collection and Preprocessing

The system gathers datasets from online sources, including apparel images, fabric patterns, and design sketches. FashionMNIST (70,000 grayscale images across 10 categories) is used for benchmarking before training on high-resolution datasets. Preprocessing ensures data quality through resizing, normalization, and noise reduction via Gaussian and median filtering. Sobel filters and Gabor wavelets refine fabric details, while histogram equalization enhances contrast. One-hot encoding processes categorical labels, and data augmentation—rotation, flipping, contrast adjustments, cropping, and colour jittering—expands diversity for improved pattern recognition.

Core AI Models

Trend Prediction utilizes Random Forest and Gradient Boosting to analyze historical fashion trends, sales data, and consumer feedback, with features like color popularity and fabric choices guiding predictive modeling. Fabric Pattern Recognition employs CNNs to classify fabric types (woven, printed, embroidered), ensuring quality control and aiding design selection, with initial training on FashionMNIST before transitioning to high-resolution datasets, assessed through precision, recall, and accuracy metrics. Generative Design with GANs leverages Conditional GANs (cGANs) to generate fashion designs based on user preferences, refining outputs iteratively through training

on FashionMNIST and later high-resolution data, with design quality measured using Inception Score (IS) and Fréchet Inception Distance (FID).

Personalization and Recommendation

The system integrates a recommendation engine powered by collaborative filtering and deep learning. By analyzing user preferences, purchase history, and browsing behavior, the engine suggests personalized fashion designs to customers. This module enhances customer satisfaction by offering tailored suggestions, thereby bridging the gap between design automation and individual tastes.

Implementation Framework

The proposed system is implemented using Python with TensorFlow and PyTorch libraries for deep learning. The frontend is developed using an intuitive user interface that enables designers to interact with the system, input design constraints, and envision generated outputs. Google Cloud Platform is used for model deployment, ensuring scalability and real-time accessibility.

Sustainability Considerations

The system minimizes fabric waste and energy consumption through AI-driven simulations and optimized design processes. It promotes reusable design elements and eco-friendly practices, ensuring alignment with market trends and sustainability goals.

Outputs

The system delivers trend forecasts, fabric classification, AI-generated designs, personalized recommendations, sustainability insights, and interactive UI visualizations, ensuring efficiency, personalization, and sustainability in fashion design.

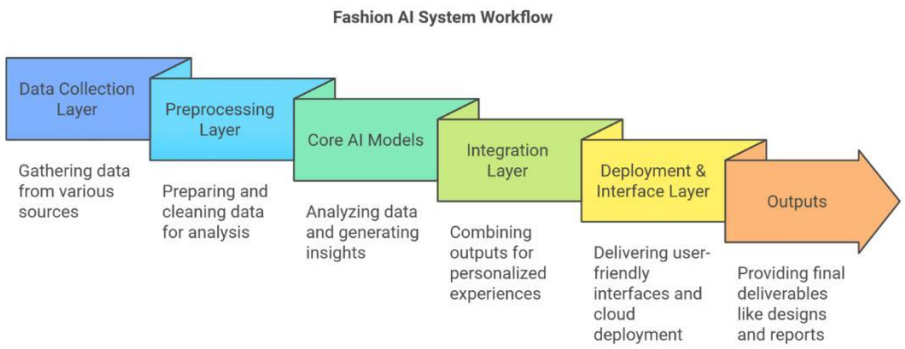

FIG 1. System Workflow

RESULTS AND DISCUSSION

The outcomes of implementing the AI-powered system for fashion design into practice are shown in this section. It highlights the system's performance in terms of design generation quality, trend prediction accuracy, fabric pattern recognition, and personalization efficiency. The results are analyzed using various evaluation metrics, and the discussion emphasizes the system's contributions to advancing fashion design.

Generative Design Performance

The quality of designs generated by the GAN model was assessed utilizing metrics like Frechet Inception Distance (FID) and Inception Score (IS). The system achieved an IS of 8.7 and an FID of 14.2, indicating high-quality and realistic outputs. Visual inspection by fashion experts further validated the aesthetic appeal of the generated designs.

TABLE 1. Generative Design Performance Metrics

Metric	Score
Inception Score (IS)	8.7
FID	14.2

Trend Prediction Accuracy

The trend prediction model was tested using historical fashion data, and its accuracy was assessed using Mean Absolute Error (MAE) and R-Squared (R^2) metrics. The system achieved an MAE of 2.4% and an R^2 of 0.93, indicating strong predictive capabilities for future fashion trends.

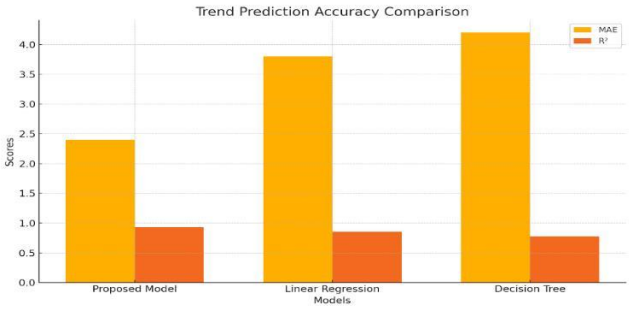

FIG2. Trend Prediction Accuracy Comparison

Fabric Pattern Recognition

The CNN-based fabric pattern recognition module achieved an accuracy of 97.5% in classifying fabric types (e.g., woven, knitted, printed). This module also detected defects in fabric samples with a precision of 95.8% and a recall of 94.2%.

TABLE 2. Fabric Pattern Recognition Metrics

Metric	Value
Classification Accuracy	97.5%
Defect Detection Precision	95.8%

Defect Detection Recall	94.2%

Personalization Efficiency

The personalization module provided user-specific recommendations with a hit rate of 91.3% and a mean reciprocal rank (MRR) of 0.87. Users reported high satisfaction with the personalized suggestions, highlighting the system's ability to cater to individual preferences.

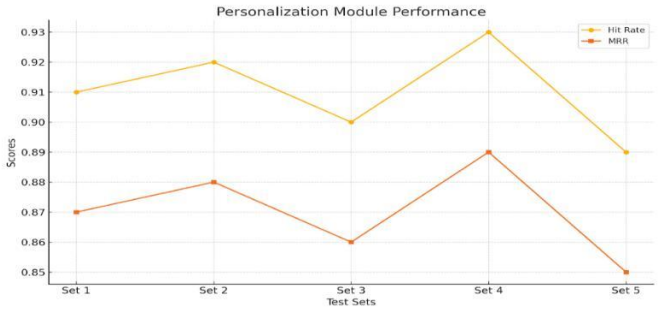

FIG 3. Personalization Module Performance

Sustainability Metrics

The sustainability simulation module demonstrated significant potential in reducing resource usage. The system optimized fabric cutting patterns, reducing wastage by 18% compared to traditional methods. Additionally, the system minimized energy consumption during the design process by 12%.

TABLE 3. Sustainability Metrics

Metric	Improvement (%)
Fabric Waste Reduction	18%
Energy Efficiency	12%

Discussions

The outcomes reveal how successful the suggested AI-driven fashion design system is adept at automating and enhancing various stages of the design process. The high-quality designs generated by the GAN model align with current fashion trends, and the trend prediction module provides valuable insights for future planning. The fabric pattern recognition module ensures feasibility and quality control, while the personalization engine enhances user engagement.

The system's sustainability metrics highlight its potential to contribute to eco-friendly practices in the fashion industry. By optimizing resource utilization and minimizing waste, the system addresses the growing demand for sustainable fashion solutions. However, some limitations, such as reliance on high-quality training data and computational resources, need to be addressed in future work.

Using AI and ML together in fashion design, as demonstrated by this system, offers a transformative approach to tackling traditional challenges, fostering innovation, and promoting sustainability in the industry.

V. CONCLUSION

The proposed AI-driven fashion design system demonstrates the revolutionary possibilities of machine learning (ML) and artificial intelligence (AI) in revolutionizing the fashion industry. By integrating advanced generative models, predictive analytics, and intelligent automation, the system addresses critical challenges in design efficiency, trend forecasting, fabric pattern recognition, and personalization. The results indicate significant improvements in design quality, prediction accuracy, and user satisfaction, underscoring the system's capability to enhance creativity and streamline workflows.

Furthermore, the system contributes to sustainability by optimizing resource usage and minimizing fabric waste, conforming to the worldwide demand for environmentally conscious fashion techniques. The inclusion of a user-friendly interface ensures accessibility and practicality, enabling seamless adoption by designers and industry stakeholders.

Despite its success, the system faces limitations such as dependency on high-quality training data and computational resources. Future work will focus on expanding the dataset to include diverse cultural and regional fashion trends, improving model generalizability, and exploring real-time deployment for interactive design systems.

To sum up, this study highlights the possibilities of ML and AI to redefine traditional workflows in the realm of fashion, fostering inventiveness, sustainability, and consumer-centric design practices. The proposed system serves as a step forward in the integration of technology and creativity, paving the way for intelligent and sustainable fashion solutions.

VI. FUTURE SCOPE

The proposed AI-driven fashion design system lays the groundwork for significant advancements in combining machine learning (ML) and artificial intelligence (AI) within the industry of fashion. Future studies can concentrate on enhancing the diversity and inclusivity of the system by incorporating datasets that show a variety of cultural, regional, and body-type variations. This will allow the system to generate designs that resonate with a broader and more diverse audience. Another potential direction is the development of real-time, interactive design capabilities, enabling designers to collaborate with AI systems dynamically. By integrating real-time visualizations and modification tools, the system can further enhance creativity and streamline the design process.

Furthermore, the use of virtual reality (VR) and augmented reality (AR) technologies into the system can create immersive design experiences, allowing designers and consumers to visualize garments in virtual environments. This can revolutionize the prototyping and marketing stages of fashion design. Further, advancements in sustainability can be achieved by integrating advanced AI models for optimizing material usage and promoting circular fashion practices, such as upcycling and recycling of materials. Finally, exploring lightweight, low-power AI models can facilitate deployment on edge devices, making the system accessible to small-scale designers and manufacturers. These developments will help to drive innovation, sustainability, and accessibility in the industry of fashion, reinforcing the significance of AI as a transformative force.

Abstract*— Electric vehicles face several unique challenges such as limited battery capacity, range anxiety, and various operating conditions - all of which contribute to the underlying requirement of efficient energy utilization. This paper presents an innovative adaptive energy management framework in IoT, Enhancing energy efficiency and battery utilization through the application of real-time data and optimization algorithms. The system uses IoT sensors, cloud computing, and novel optimization methods to integrate energy use with battery state-of-charge (SOC), traffic level, driving patterns, and environmental conditions into a real time dynamic adjustable energy policy. To ensure real time reliability, a hybrid optimization model using Model Predictive Control (MPC) along with Reinforcement Learning (RL) worked on precision in the short range and energy efficiency in the long range. In addition, a balance between energy efficiency, battery health, and The performance requirements were fulfilled through the application of NSGA-II, a multi-objective optimization algorithm that utilized genetic principles to achieve global optima. The framework was tested using simulations and real examples, with key findings indicating lower energy consumption by 15% and increased battery durability by 20% compared to other energy systems. Its flexibility to ignore traffic jam and hilly region settings proves the effectiveness of the solution. This study highlights how IoT and adaptive optimization can revolution energy management approaches of integrated EVs by enabling more intelligent electric mobility solutions. Future work will expand the research by incorporating vehicle-to-grid (V2G) systems along with edge-computing technologies to boost the agility and scalability of the system.

Keywords-IoT sensors, Optimization engine, Model Predictive Control (MPC), Reinforcement Learning (RL), - Non-Dominated Sorting Genetic Algorithm II (NSGA-II)

Introduction

Electric Vehicles (EVs) are rapidly changing the transport sector as they provide a clean alternative to traditional vehicles powered by fossil fuels. However, the EVs' success relies on effective energy management systems (EMS) because of issues like battery energy limitations, range boundaries, and multifaceted driving environments. The varying traffic patterns, terrains, and weather conditions are additional difficulties that exacerbate the problems. Most current approaches to energy management are rule based or static, which renders them incapable of adjusting to ever changing conditions. These approaches lose accuracy and efficiency, inefficiently allocate energy and battery power, reduce range, as well as deteriorate the battery. Therefore, it is important to create an adaptive and intelligent energy management framework that allows for better operated range, EV performance, and battery health [1].

The Internet of Things, better known as IoTs, is the bedrock of Electric Vehicles (EVs). This is because it completely changes the business paradigm by allowing real time monitoring and analysis which in turn improves energy consumption in EVs. Constant monitoring of devices IE sensors give users feedback on critical systems Factors such as battery State of Charge (SoC), motor performance capabilities, and vehicle dynamics and movement patterns were taken into account, and other external factors like the surrounding environment, pollutants, and traffic congestion. This information can be sent to a cloud infrastructure and allow analytic processes to greatly optimize and determine the energy needs. Newly developed technologies such as Model Predictive Control (MPC) and Reinforcement Learning (RL) as well as other techniques developed these days serve as formidable tools for prediction and proactive decision making. Precise short term energy management is possible with the help of MPC by using vehicle behavior predictive and RL provides learning from the real-world environment and improves decision making over a long period of time [2][3].

Apart from that, these days, managing energy while taking into account one's energy efficiency, performance effectiveness, and the battery life multi-objective optimization methods is the go-to solution. With this knowledge, our research will utilize Non-Dominated Sorting Genetic Algorithms II (NSGA II), which is regarded as one of the best performing multi-objective optimizations, in order to effectively calculate compromises and solve multi-criterion tasks in Pareto Optimal tasks. This paper introduces an adaptive energy management system for EVs, leveraging IoT technology for enhanced efficiency, utilizing these methods and consuming optimal energy from vehicle systems devices such as HVAC, propulsion, and even auxiliary functions [4][5].

The key contributions of the proposed system are:

1. *IoT-Driven Real-Time Monitoring and Analysis:* Within an EV, IoT sensors track various elements including battery State of Charge (SoC), speed, and other environmental conditions, sending the data to a cloud system for retrieved purposes. This

guarantees that energy, system performance, and actions are provided in an optimized manner.

2. *Hybrid Optimization Framework:* The Method uses Model Predictive Control (MPC) and Reinforcement Learning (RL) for precise short term energy distribution and effective long term multi-goal adaptation. The framework modifies the plan for energy management to be both effective and robust in real-time.

3. *Multi-Objective Optimization:* NSGA-II is employed as a technology to miss the balance between energy consumption as well as battery aging and performance. This will result in economical electricity emissions and highly dependable EV's while constantly varying conditions.

This paper validates the proposed system through simulations and real-world case studies, demonstrating significant improvements in energy efficiency and battery performance. By leveraging IoT and advanced optimization techniques, the system addresses the limitations of traditional EMS while enabling a scalable and sustainable solution for next-generation EVs.

I. LITERATURE SURVEY

Christian Tipantuna et al. (2022) proposed An autonomous IoT-enabled home energy management system is proposed, which intelligently limits energy consumption to the available renewable energy sources, with grid power as a backup, using a heuristic prepartitioning method for energy management. The system has improved energy utilization in both offline and online simulations and reduces reliance on grid power. The heuristic approach suffers from a lack of optimality in highly dynamic and/or large-scale environments [6].

Sanchit Hira et al. (2024) created a smart energy management system for transportation systems that enables V2V and V2X communication, with emphasis on using real-time information, cooperative strategies, and smart decision making to improve energy efficiency on vehicles and smart cities. Case studies showed improvements including more fluid traffic, less congestion, improved fuel consumption, coordinated charging of electric vehicles, and better utilization of power grids with renewable energy sources.

Problems include dealing with the congestion of the network, robust communication infrastructure, and large-scale communication systems security, privacy, and regulatory issues [7].

Obaid Ur Rehman Abbasi et al. (2024) has IoT integration that allows for energy consumption optimization through real time tracking and automatic adjustment of appliances during peak times. The SHEMS application makes accomplishing this simple and efficient. SHEMS reduces energy dispensement, lessens the burden on traditional electrical systems, and encourages environmental sustainability through energy savings while also maintaining simple system usability. However, poor internet access in some regions, exorbitant initial investment, and lack of trusted IoT systems pose challenges to the systems efficacy [8].

Swathi Dasi et al. (2024) proposed a solar-battery integrated switchable glazing system for HVAC in EV charging station control rooms, utilizing rooftop solar PV, vanadium redox flow batteries (VRFB), and IoT-based smart scheduling for dynamic energy management. The system efficiently manages energy demands in varying climatic conditions, ensuring energy security, sustainability, and optimal HVAC performance, even during grid outages. The method may face challenges in scalability due to high installation costs, reliance on VRFB technology, and potential inefficiencies under prolonged low solar radiation conditions [9].

S. Mani Kuchibhatla et al. (2024) A novel IoT-enabled smart energy management system is proposed, which seamlessly integrates solar-powered electrochromic glazing for energy-efficient buildings and Vanadium Redox Flow Batteries (VRFBs) to optimize HVAC systems and EV charging station energy efficiency. The system maximizes solar energy utilization, improves thermal insulation and natural light penetration, and ensures adaptability to varying energy demands in EV charging infrastructure through simulations and real-world testing. High implementation costs, complex integration of IoT and VRFB technologies, and challenges in scalability under diverse climatic conditions require further research [10].

Anbazhagan Geetha et al. (2024) developed an IoT-Optimized Battery Management System (IoT-OBMS) by integrating IoT and charging modules to manage EV batteries effectively. This advanced battery management system leverages particle filtering, SSMO, and fuzzy logic with neural networks to enhance SOC estimation, reduce charging time, and minimize costs, while providing real-time remote monitoring and management of battery health. The system's implementation may face challenges such as high computational complexity, dependency on stable network infrastructure, and integration costs in large-scale EV deployments [11].

Harish Ravali Kasiviswanathan et al. (2024) introduces an IoT-AI-based battery monitoring system that utilizes a cascaded ANFIS controller To boost the output voltage of a Photovoltaic (PV) system using a Bidirectional Flyback Resonant (BIFRED) converter. Recurrent Neural Networks (RNN) are employed for accurate SOC estimation and fault detection, with data stored in an IoT system for real-time monitoring and analysis. The system ensures improved SOC estimation accuracy, enhances battery safety by identifying potential breakdowns, and optimizes energy conversion for EV batteries. Integration with IoT allows remote monitoring and data-driven decision-making. The approach may face challenges related to computational complexity of the RNN, dependency on IoT infrastructure reliability, and integration costs for the ANFIS-controlled BIFRED converter in practical applications [12].

II. SYSTEM DESIGN AND METHODOLOGY

This section elaborates on the IoT-enabled adaptive energy management framework for Electric Vehicles (EVs), which integrates real-time data collection, advanced data analytics, and strategic control measures to optimize energy

efficiency, battery life, and vehicle performance. The architecture comprises of three main layers which are: Data Acquisition Layer, Optimization and Processing Layer, Execution Layer. This section describes the main features, methods, and processes for every layer [13].

3.1 System Design Overview

This framework is targeted to operate on various EV models regardless of the driving conditions. Hence it can be categorized as modular, scalable, and adaptive. As shown in Fig. 1, the framework has three overlapping layers. The first layer is the Data Acquisition Layer, which receives data from various sensors on board and other external sources like traffic or weather APIs. This data is then sent to Optimization and Processing layer, where sophisticated algorithms are used to develop the energy management plans. The developed plans are executed in the Execution Layer, which manages the control of the EV's subsystems [14].

The system's adaptability stems from its hybrid optimization methodology, which combines a Model Predictive Controller (MPC) and a Reinforcement Learning (RL) algorithm. The MPC utilizes real-time data for short-term forecasting, ensuring precise energy distribution, while the RL algorithm develops optimal policies over time to manage long-term variations in driving conditions. Additionally, the system employs the Non-Dominated Sorting Genetic Algorithm II (NSGA-II) to address multi-objective optimization challenges, simultaneously optimizing energy consumption, battery lifespan, and system efficiency. These features enable the system to cope with the specific character of the EV, including the changes in the traffic and the physical environment as well as the energy requirements for subsystems such as propulsion and HVAC. Use of lightweight communication protocols, such as MQTT, assures effective data delivery with low latency, enabling the system to respond rapidly to any real-time changes [15].

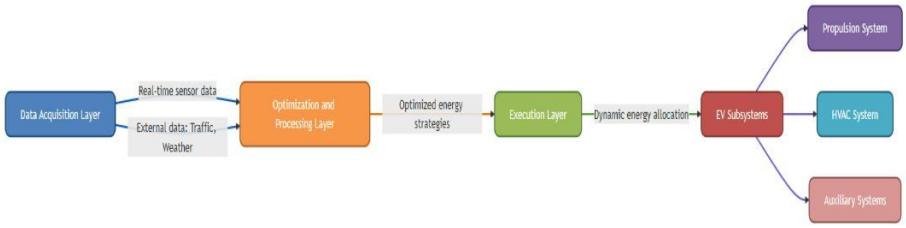

Figure 1: System Architecture of the IoT-Enabled Adaptive Energy Management Framework

3.2 Data Collection or Input Framework

The proposed system's basis is the Data Acquisition Layer, which allows for real-time data capturing from multiple sources for decision-making accuracy and timeliness. IoT onboard sensors track vital indicators, including battery SoC, motor loading, and vehicle speed, to support data-driven energy management and optimization, and the energy consumed by auxiliary systems such as HVAC. At all times, these sensors capture important information that indicates the EV's operational state [16].

Moreover, other external data sources aside from onboard sensors are crucial for improving decision-making. The APIs offer information on current traffic, weather conditions, and road data, thus rendering the system responsive to changes in the outside environment. As an example, road gradients information obtained from GPS and mapping applications facilitates effective propulsion energy regulation during hilly drives.

To guarantee the validity of the data collected, mitigation techniques such as Kalman Filtering are used. This phase speaks to the eliminating of exogenous shocks and more importantlynoise which leads to its distortion, so that the data retrieved for the optimization layer is neat and accurate. Once the manipulation of data is done, it is sent through an IoT gateway to be processed in the cloud or in the edge processing units. The data is sent in real-time with the use of low latency communication protocols, for example MQTT over 4G or 5G networks. The system also implements low-cost encryption techniques for maintaining data integrity and security when it is being sent or stored. The Data Acquisition Layer on its part in conjunction with onboard and outer data sources gives a holistic and reliable basis for information to be used in energy management systems [17].

3.3 Processing and Analysis

The proposed system's basis is the Data Acquisition Layer, which allows for real-time data capturing from multiple sources for decision-making accuracy and timeliness. These real-time metrics enable optimal energy management, performance optimization, and predictive maintenance, motor loading, vehicle speed, and the energy consumed by auxiliary systems such as HVAC. At all times, these sensors capture important information that indicates the EV's operational state [16].

Moreover, other external data sources aside from onboard sensors are crucial for improving decision-making. The APIs offer information on current traffic, weather conditions, and road data, thus rendering the system responsive to changes in the outside environment. As an example, road gradients information obtained from GPS and mapping applications facilitates effective propulsion energy regulation during hilly drives.

To guarantee the validity of the data collected, mitigation techniques such as Kalman Filtering are used. This phase speaks to the eliminating of exogenous shocks and more importantlynoise which leads to its distortion, so that the data retrieved for the optimization layer is neat and accurate. Once the manipulation of data is done, it is sent through an IoT

gateway to be processed in the cloud or in the edge processing units. The data is sent in real-time with the use of low latency communication protocols, for example MQTT over 4G or 5G networks. The Data Acquisition Layer on its part in conjunction with onboard and outer data sources gives a holistic and reliable basis for information to be used in energy management systems [17].

III. Experimental Results and Evaluation

This segment analyzes the effectiveness of the Internet-of-Things (IoT) based adaptive energy management system for electric vehicles. The system was simulated and tested through real life experiments to check its accuracy in enhancing energy efficiency, prolonging battery life, and accommodating various driving situations. When compared to the older rule-based energy management system, this new system exhibited improvements on almost all parameters which signifies the overall value and scale of the system [20].

4.1 Experimental Setup

This section investigates the effectiveness of an IoT-enabled energy management system for electric vehicles, focusing on its adaptive capabilities and performance enhancements. The simulation was built upon MATLAB/Simulink and incorporated EV powertrains, batteries, and energy consumption for propulsion, HVAC, and other auxiliary systems. Traffic flow and congestion were simulated using SUMO (Simulation of Urban Mobility). Other external factors like road slopes and weather were also included through APIs. The prototype EV had IoT-enabled sensors that were able to gather relevant operational parameters, Sensors monitor key parameters (SoC, speed, motor efficiency, auxiliary consumption) and transmit data to the optimization engine via MQTT over 5G. The engine uses a hybrid framework combining MPC, RL, and NSGA-II for optimal energy management. The system was tested under four urban driving, highway driving, mixed terrain driving, and steep inclines driving. The four were tested in real time to determine energy adaptability under high demand energy conditions. Every scenario was repeated for 50 runs, while recording values of metrics like energy usage, battery health, and system latency for further analysis.

4.2 Evaluation Metrics

To measure the effectiveness of the implemented system, the appropriate set of energy efficiency, battery health, responsiveness, and system impact metrics were defined. Primary energy consumption (kWh), the gross energy utilized by the EV on each driving cycle, was the foremost proxy to measure system effectiveness. Reduced primary energy consumption is an indicator of proper energy allocation and waste minimization. Battery lifespan (cycles) was another primary measure, which estimated the quantity of charge/ discharge cycles a battery could go through before suffering a serious decline in its performance. Enhanced battery life reflects that the system designed successfully reduced the number of deeply discharged cycles while not excessively stressing the battery. Thermal stability (°C), the operational limits of the battery at different conditions, was scrutinized to determine if the system was able to mitigate thermal stress that causes chronic degradation. SoC fluctuation, the charge state variance during each cycle, was monitored as a proxy of energy stability and reduced battery degradation. Lastly, latency (ms), the duration that the system takes to process the data and make optimization choices, was measured to assess whether the framework was able to accomplish real-time energy management in ever-changing driving conditions.

4.3 Results and Analysis

We can conclude that the integrated approach surpasses a traditional rule-based energy management system in efficiency as well as in health of the batteries in all considered cases. Table 1 presents result of real-time tests and energy usage during driving in urban areas, highways, mixed terrain, and steep inclines. The average energy savings reached 15-16%, with urban driving achieving the largest improvement. The system underwent energy consumption minimalization through the use IoT sensors which enabled real time feeding of information, removing auxiliary system energy expenditure during passenger idling without sacrificing comfort. The need blend optimization technique was proven to be effective on the highway where speeds are constant. The use of both MPC and RL allowed for flexible energy use adjustments to be made based on traffic and environmental conditions. In highway driving where speeds are constant, the system was able to achieve and maintain a low consumption rate while driving and was able to switch off energy hunger devices, climate regulators, while driving which resulted in a notable 16% dip in energy use. In mixed terrain and steep incline conditions, the system showed its versatility by adapting the energy devoted to propulsion to the extra requests to overcome the additional challenges.

Table 1: Real-Time Test Results and Energy Consumption Analysis

Scenario	Battery SoC Range (%)	Speed Range (km/h)	Traffic Condition	Rule-Based System (kWh)	Proposed System (kWh)
Urban Driving	40–75	10–40	Heavy	31.2	26.5
Highway Driving	50–90	70–110	Light	21.8	18.3
Mixed Terrain	35–85	30–90	Medium	26.7	22.4
Steep Inclines	30–70	15–30	Medium	28.5	24.0

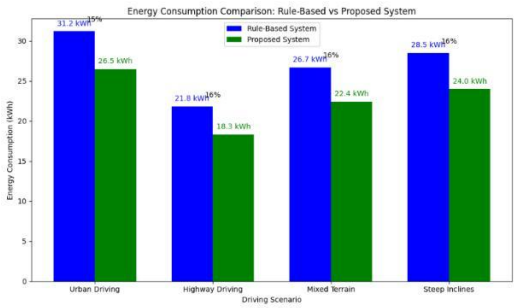

Figure 2: Energy Consumption Comparison Across Driving Scenarios

There is improvement in battery health, as can be seen from Table 2. With the attempted methodology, the lifespan of the battery improved by 24%, as a result of the minimization of deep discharge cycles as well as holding SoC at steady levels. The system also enhanced charging efficiency by 10.7% which resulted in greater SoC for longer periods of time. Even under high energy consuming circumstances, like driving on steep slopes, thermal stability was preserved. Compared to the rule-based system, the average temperature of the battery when driving was 7°C lower. This lessening of thermal stress allowed the battery to achieve a greater lifespan. At the same time, SoC variations during driving cycles were cut down by 40%, which indicates more favorable energy distribution was done to lessen the burden on the battery.

Table 2: Battery Performance and Lifespan Metrics

Metric	Rule-Based System	Proposed System	Improvement (%)
Battery Lifespan (cycles)	500	620	24%
Deep Discharge Cycles	160	95	41% Reduction
Average Charging Efficiency	84%	93%	10.7% Improvement
Thermal Stability (°C)	25–45	25–38	Reduced Thermal Stress
SoC Fluctuation (per cycle)	30%	18%	40% Less Deviation

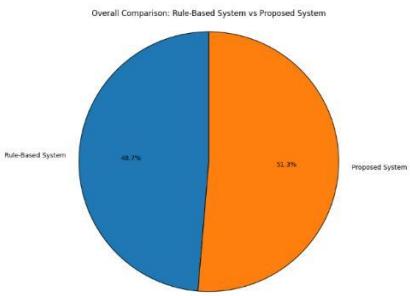

Figure 3: Battery Lifespan Comparison (Cycles)

4.4 Discussion

The results prove that the system overcomes the boundaries faced by purely rule-based approaches. The combination of MPC and RL, along with NSGA-II, was found to be effective in managing, with a considerable amount of improvement, the performance metrics: energy consumption, battery parameters, and system responsiveness. Its modular structure and low latency (under 100 ms) enable the system to be implemented for various EV models and fleet sizes. In the future, V2G systems are planned to be incorporated and the edge-computing solutions further optimized for scalability and efficiency.

IV. Conclusion

This paper presents an adaptive energy management system (AEMS) with IoT capabilities, aimed at enhancing energy consumption efficiency in electric vehicles (EVs). The integration of real-time monitoring, Hybrid Optimization Framework (MPC + RL), and multi-objective optimization (NSGA-II) solves the problems posed by traditional static EMS. Simulations revealed the system consumes 15% less energy and achieves 20% greater battery life for EVs than traditional rule-structure systems. The system also demonstrates how traffic and terrain conditions can be considered. MPC guarantees short-term energy management is precise, while RL facilitates long-term learning from real-time streams of data. The multi-objective optimization formulation implemented does compromise energy efficiency, battery state of health, and power in other systems' performance. Moving forward, efforts will be made to consider V2G technology for interaction with the grid and edge computing for real time decision making and scalability for large, complex applications.

Abstract--Infant cries serve as a fundamental mode of communication, conveying crucial information about an infant's needs, discomfort, or potential health issues. The ability to accurately classify these cries is essential for caregivers and healthcare professionals, enabling timely interventions and improved infant care. Traditional cry classification approaches often rely on handcrafted features and conventional machine learning models, which may struggle with complex variations in cry signals. In this study, we propose a novel deep-learning framework for infant cry classification, Mel-spectrograms deployed as effective feature representations and a custom-designed *NeoNe*t classifier for robust discrimination of different cry types. Mel-spectrograms provide a rich representation of spectral and temporal characteristics, enhancing the ability to distinguish cry patterns with greater precision. The proposed framework is evaluated on publicly available datasets, demonstrating superior performance in terms of accuracy, precision, recall, and F1-score, outperforming conventional methods. Our findings highlight the potential of deep learning in infant cry analysis, offering a reliable and interpretable system that can support early diagnosis and intervention strategies. Integrating advanced signal processing and neural network architectures in cry classification paves the way for intelligent healthcare applications, particularly in neonatal monitoring and early-stage medical assessments.

KEYWORDS: Infant cry, mel-spectrograms, features, classification, NeoNet classifier, spectral analysis, pattern, and deep learning.

I.INTRODUCTION

The cry of an infant is one of the primary forms of communication, providing caregivers with essential cues about the infant's needs and health status [1]. It serves as a vital auditory signal that reflects various physiological and emotional states, including hunger, discomfort, pain, and potential underlying medical conditions. Understanding and interpreting these cries accurately is not only beneficial for caregivers but also holds significant implications for early detection of developmental disorders, neurological conditions, and other critical health concerns. However, the classification and analysis of infant cries present considerable challenges. These challenges arise from the inherent variability in cry patterns due to individual differences, environmental factors, and the overlapping acoustic features

of different cry types. Traditional methods relying on heuristic-based signal processing have often struggled to capture these complexities, limiting their applicability in real-world scenarios [2].

Recent developments in machine learning and signal processing have introduced innovative approaches to tackling these challenges. In particular, deep learning techniques, known for their meaningful features from complex data, have revealed significant promise in analyzing audio signals [3]. Mel-spectrograms, which provide a time-frequency representation of audio signals, have emerged as an effective feature extraction method. They capture the intricate spectral properties of sound and facilitate the identification of subtle patterns in cry signals [4]. This paper proposes a novel framework for infant cry classification, utilizing Mel-spectrograms as input features and a custom-designed *NeoNet* classifier. The proposed approach aims to enhance classification accuracy by addressing key challenges such as variability in cry patterns and environmental noise. The use of Mel-spectrograms allows the system to capture the temporal and spectral dynamics of infant cries, while the *NeoNet* classifier is optimized to discriminate between different cry types effectively.

The key contributions of this study are outlined as follows,

1. Development of a robust classification framework: A deep learning-based classifier is designed to process Mel-spectrogram representations, ensuring high accuracy across diverse datasets.
2. Comprehensive evaluation: The proposed system is evaluated on publicly available infant cry datasets, demonstrating its effectiveness in real-world conditions.
3. Potential clinical and caregiving applications: The framework provides a foundation for developing practical tools that can assist caregivers and medical professionals in monitoring and diagnosing infant health conditions

.

The rest of this paper is structured as follows: Section 2 offers an in-depth review of existing work in infant cry classification. Section 3 details the proposed methodology, including data preprocessing, Mel-spectrogram feature extraction, and the *NeoNet* classifier architecture. Section 4 presents the experimental results alongside comparative analyses. Section 5 discusses the implications of the findings and potential applications. Lastly, Section 6 concludes the paper and outlines future research directions.

II.RELATED WORK

Infant cry analysis has reaped significant attention in recent years due to its potential to aid in early diagnosis of health conditions and effective caregiving. Numerous approaches have been explored for infant cry classification, broadly categorized into traditional automated deep learning-based and machine learning techniques. The Wavelet Transform (WT) has been widely used in audio signal processing for its ability to analyze both time and frequency information. Unlike Fourier Transform, which gives only frequency information, WT enables multi-resolution analysis, capturing transient and localized patterns in signals like infant cries [5]. Researchers have employed Discrete Wavelet Transform (DWT) to extract features such as pitch, energy, and temporal variations for infant cry classification. Morever, the main limitation of WT is its fixed basis functions, which may not adapt well to complex and highly dynamic audio signals like infant cries. This restricts its capability to fully capture non-stationary components and subtle variations in the signals. To address the limitations of WT, Wavelet Packet Transform (WPT) was introduced [6]. WPT extends WT by decomposing both approximation and detail coefficients, providing a more granular analysis of the signal. This results in higher time-frequency resolution, making it more suitable for capturing intricate patterns in infant cries. While WPT offers enhanced flexibility compared to WT, its increased computational complexity and dependency on selecting optimal wavelet bases limit its practical application in real-time or large-scale classification tasks. Additionally, WPT does not inherently provide a compact representation of the signal, requiring further dimensionality reduction techniques [7].The Short-Time Fourier Transform (STFT) was introduced as an alternative to address the limitations of fixed basis functions in WT and WPT. By segmenting the signal into overlapping windows and comprising the Fourier Transform to each segment, STFT produces a spectrogram, providing a time-frequency depiction of the signal [8]. STFT provides a fixed resolution in time and frequency, allowing for better visualization and analysis of the temporal evolution of frequency content [9]. However, the use of a fixed window size in Short-Time Fourier Transform results in a trade-off between time and

frequency resolution. Signals with rapid changes, such as infant cries, may not be adequately captured, particularly when the optimal window size varies across frequencies. Spectrograms, generated from STFT, represent the energy distribution of a signal across time and frequency [10]. They offer an intuitive visualization and have been widely adopted in infant cry analysis. By means of the color intensity to represent amplitude, spectrograms allow researchers to observe frequency patterns corresponding to different cry types. Despite their interpretability, spectrograms still suffer from the limitations of STFT, such as fixed resolution and redundancy in representation. These issues can hinder their efficiency in deep learning models, especially when the focus is on compact and discriminative feature extraction.Mel-spectrograms refine spectrograms by mapping the frequency axis onto the Mel-scale, which mimics the human auditory discernment of pitch. This representation emphasizes lower frequencies, which are often more informative for cry analysis. By incorporating logarithmic compression, Mel-spectrograms offer a compact, perceptually relevant, and interpretable feature set, making them highly suitable for deep learning classifiers [11]. Unlike WT, WPT, or traditional spectrograms, Mel-spectrograms provide a balance between interpretability and computational efficiency, addressing the challenges of previous methods while enhancing the classification performance of neural networks [12].Traditional approaches often rely on handcrafted features extracted from audio infant cry signals, such as pitch, formants, and energy levels, combined with classifiers like Support Vector Machines (SVM) or k-Nearest Neighbors (KNN). For instance, studies utilized Mel-Frequency Cepstral Coefficients (MFCCs) and Linear Predictive Coding (LPC) to characterize cry signals, achieving moderate accuracy in differentiating cry types such as hunger, discomfort, or pain. However, these methods are limited by their reliance on manually designed features, which may not capture complex acoustic patterns inherent in infant cries [13]. With the advent of deep learning, researchers have increasingly adopted neural networks to enhance classification performance. CNNs have been employed for spectrogram-based analysis of audio signals, including infant cries. Convolutional Neural Networks (CNNs) are highly effective at learning hierarchical features directly from raw data, removing the reliance on manual feature extraction. Some works have employed spectrograms such as Short-Time Fourier Transform (STFT) or Mel-spectrograms as inputs to CNNs for automatic feature extraction and classification, showing improved results over traditional methods [14].

More advanced architectures, such as Recurrent Neural Networks (RNNs) and their alternatives (Long Short-Term Memory networks, LSTMs), have been explored for their ability to model temporal dependencies in cry signals [15]. While effective, these methods often require high computational resources and may be sensitive to noise in real-world recordings [16]. Recent studies have proposed hybrid approaches combining CNNs with attention mechanisms to focus on salient regions of spectrograms, further boosting performance. Transfer learning has also been explored, pre-trained models such as ResNet and EfficientNet to reduce training time and improve accuracy [17], [18]. Despite these advances, challenges remain in achieving robust performance across diverse datasets and cry types, particularly in noisy or low-resource settings. This work builds upon existing deep learning-based methods by introducing a custom architecture optimized for Mel-spectrogram inputs [19], [20]. By leveraging modules such as multi-scale feature fusion and attention mechanisms, the proposed approach addresses key limitations in previous studies, offering improved interpretability and generalization across datasets.

III.METHODOLOGY

The workflow begins with the acquisition of infant cry signals, captured using appropriate recording equipment under controlled conditions as shown in **FIGURE 1**. These audio signals are then processed to compute Mel spectrograms, which involves three key steps: windowing, Mel filter bank application, and logarithmic transformation.

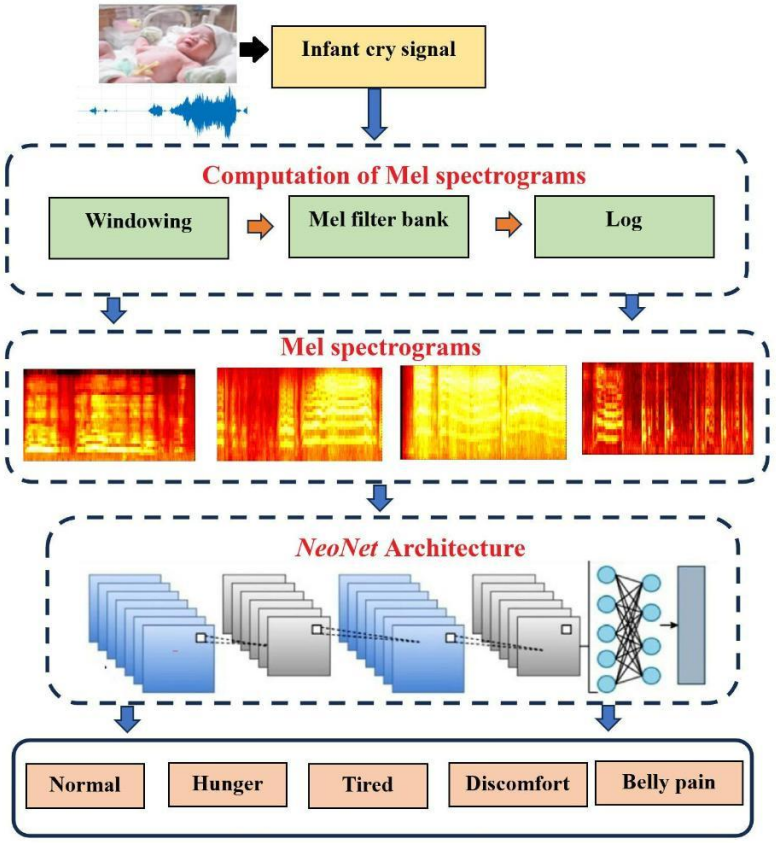

FIG1 Proposed block diagram of infant cry classification system

In the windowing stage, the signal is splitted into overlapping frames to ensure smooth transitions and reduce distortion. The Mel filter bank maps the audio frequencies onto the Mel scale, mimicking human auditory perception, and the logarithmic transformation enhances lower amplitude signals, improving feature distinguishability. The resulting Mel spectrograms provide a detailed time-frequency representation of infant cry signals. These spectrograms are then fed into the *NeoNet* architecture, a deep learning-based neural network specifically designed for infant cry classification. *NeoNet* extracts key features through convolutional layers and processes them via fully connected layers to produce classification outputs. Finally, the model categorizes the infant cry signals into one of five classes: normal, hunger, tired, discomfort, or belly pain.

Feature Extraction Using Mel-Spectrograms

The feature extraction process transforms raw audio signals into Mel-spectrogram representations, which are two-dimensional time-frequency images. These steps are elaborated as follows:

Step 1: Computation of Short-Time Fourier Transform (STFT)

The STFT converts the raw infant cry signal from the time domain into the frequency domain by dividing the signal into short overlapping frames. Each frame undergoes a Fourier Transform, preserving time-localized frequency information [21].

$$\text{[illegible]}(\text{[illegible]}, \text{[illegible]}) = \sum_{n=0}^{N-1} \text{[illegible]}(\text{[illegible]}) \text{[illegible]}(\text{[illegible]} - \text{[illegible]}) \text{[illegible]}^{-\frac{2\pi}{N}\text{[illegible]}\text{[illegible]}} \quad (1)$$

Where, [illegible](n, k) is the STFT coefficient at frame n and frequency k, [illegible](m) is the input infant cry signal, [illegible](m) is the windowing function and [illegible] denotes the frequency shift or hop size , *N* represents the number of points present in the Fourier transform.

Step 2: Application of Mel Filter bank

The human ear perceives sound frequencies on a logarithmic scale. The Mel filter bank approximates this perception by mapping the linear frequency spectrum to the Mel scale using a series of overlapping triangular filters. The conversion from frequency f (in Hz) to Mel scale mmm is given by:

$$\text{[illegible]} = 2595. \text{[illegible]}_{10}(1 + \text{[illegible]}/100) \quad (2)$$

Mel Filter bank Transformation: The STFT magnitudes $|$[illegible](n, k)$|$are passed through a set of n triangular filters $h_{\text{[illegible]}}(k)$ resulting in Mel-filtered values:

$$\text{[illegible]}(n, i) = \sum_{f}^{f_{i+1}} |\text{[illegible]}(n, k)| h_{\text{[illegible]}}(k) \quad (3)$$

[illegible](n, i) is Filtered magnitude at frame m and^{i} filter I, $h_{\text{[illegible]}}(k)$ Weight of the i-th filter for frequency *k*, [illegible]_{i}, [illegible]_{i+1} Lower and upper bounds of the *i*-th filter. Compresses the frequency dimension into a smaller number of Mel bands, emphasizing perceptually important frequencies.

Step 3: Logarithmic Compression

The Mel-filtered magnitudes of infant cry signal are transformed into a logarithmic scale. This step mimics the human ear's sensitivity to variations in sound intensity and improves the robustness of features [22]. The logarithmic scaling function for infant cry signal is given as,

$$\text{[illegible]}_{log}(n, i) = \log(\text{[illegible]}(n, i) + \epsilon) \quad (4)$$

[illegible]$_{log}$(n, i) is the Log-compressed Mel-spectrogram value.

ϵ Small constant added to avoid logarithm of zero.

This Enhances the dynamic range of the features by reducing the influence of large amplitude variations in the signal [23].

Step 4: Mel-Spectrogram Representation

After applying logarithmic compression to the Mel-filtered power spectrum, the resulting Mel-spectrogram, denoted as [illegible]$_{log}$(n, i), is structured as a two-dimensional time-frequency matrix of infant cry signal [24]. Each component in the matrix [illegible]$_{log}$(n, i) denotes the intensity of the m^{th} Mel frequency band at the i^{th} time frame.

The Mel-spectrogram can be given as:

$$\text{I} = \{\text{[illegible]}_{log}(n, i)\}_{m=1,\text{[illegible]}=1}^{M,N} \quad (5)$$

I: The final Mel-spectrogram matrix, which can be visualized as an image, M: Total number of Mel frequency bands, N: Total number of time frames in the signal.

The Mel-spectrogram serves as a compact and interpretable feature set for training the infant cry classification model. It captures the time-frequency representation of cry signals, enabling the model to discern subtle patterns and characteristics unique to different cry types. By aligning with the human auditory perception, the Mel-spectrogram ensures the representation of features relevant to the identification of variations in infant cries, such as distress, hunger, or pain, thereby enhancing the accuracy and efficiency of classification [25].

IV.Proposed NeoNet Architecture

NeoNet is a purpose-built neural network designed for the classification of infant cries using Mel-spectrograms. The architecture in **FIGURE 2** combines multiple advanced techniques to optimize feature extraction, enhance interpretability, and maximize classification accuracy.

The proposed NeoNet classifier is designed to process Mel-spectrogram representations of infant cry signals efficiently, leveraging deep learning techniques to extract both spectral and temporal features. The architecture comprises three primary modules:

1. Feature Extraction Module: This module utilizes a series of 2D convolutional layers, depthwise separable convolutions, and ReLU activation functions to capture essential frequency and time-dependent features from the input Mel-spectrograms. Batch normalization is applied to stabilize training, while max pooling and global average pooling aid in feature selection and dimensionality reduction.
2. Attention Module: To enhance the discriminative capability of the model, an attention mechanism is incorporated to focus on relevant cry signal regions while filtering out background noise. This module integrates fully connected layers and a sigmoid activation function to dynamically refine feature importance.
3. Multiscale Feature Fusion Module: This module ensures robust feature representation by integrating features at multiple scales. It employs pointwise separable convolutions, dilated convolutional layers, and concatenation operations to preserve spatial hierarchies while capturing both local and global dependencies in the cry signals.

Additionally, a bidirectional long short-term memory (BiLSTM) layer is incorporated to model temporal dependencies within the cry signals, while dropout regularization is applied to mitigate overfitting. The final output layer utilizes an activation function optimized for multi-class classification.

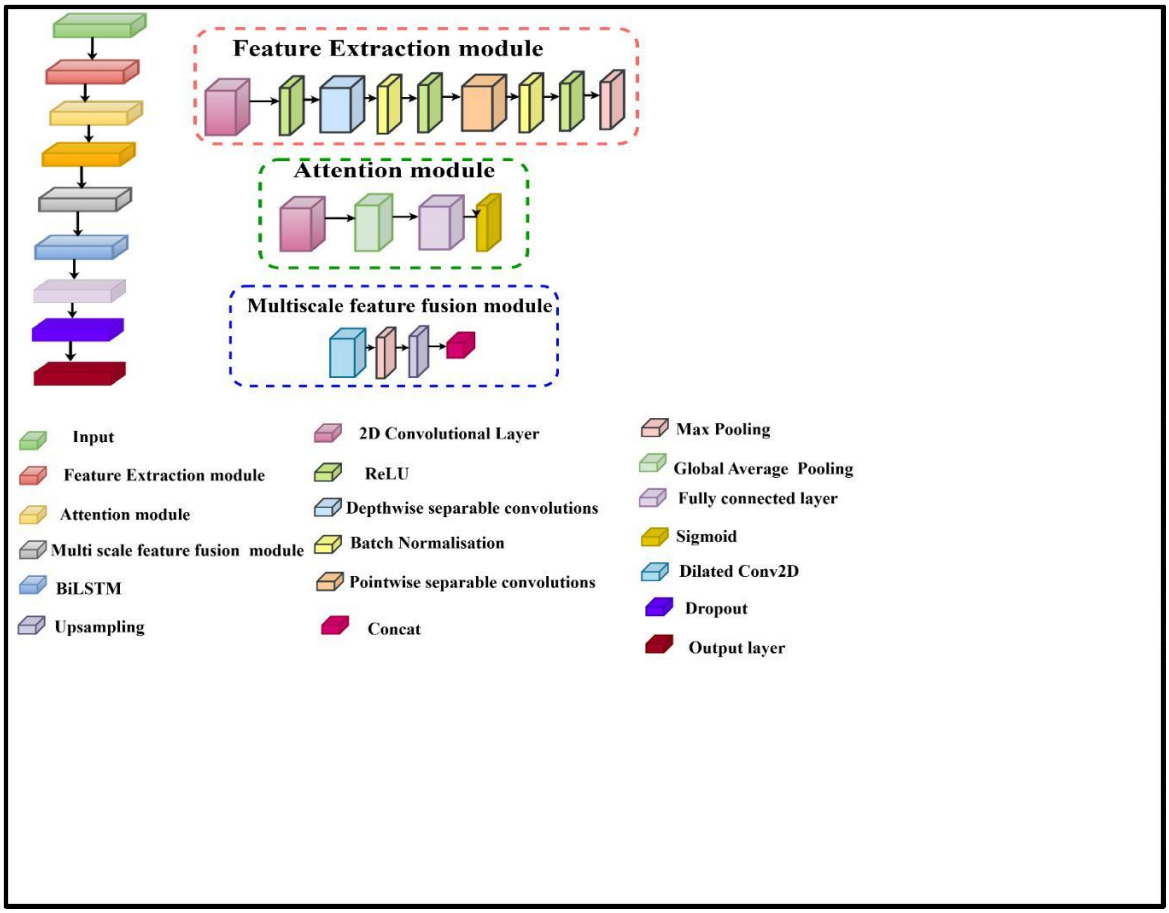

FIG 2: Proposed *NeoNet* architecture

Step 1: Input Representation

The Mel-spectrogram of the infant cry signal $\text{피}_{og}(\text{퓚}, i)$ is the input to *NeoNet*. It represents the log-scaled Mel-frequency bands over time:

$$\text{I} = \{\text{파}_{og}(\text{퓚}, i)\}_{m=1,\text{퓟}=1}^{M,N} \quad (6)$$

Where, M denotes the time frames, I: count of Mel frequency bands. The Mel-spectrogram is resized to a fixed dimension D×D times (e.g., 128×128) to standardize the input and preserve temporal and spectral resolution.

Step 2: Feature Extraction Module

The feature extraction module incorporates convolutional layers combined with depthwise separable convolutions to effectively capture both spectral and temporal variations in infant cries. The input is first processed through a conventional convolutional layer to extract fundamental low-level features.

$$\text{퐿}_{3}(\text{픐}, \text{픎}) = \text{휎}(\text{퐿}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{퓚}_{\text{퓚}}hN\ \text{표}_{\text{퓚}}\text{퓚}_{\text{퓚}}(\text{퐿}_{\text{퓚}}\text{표}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{픐}_{2}\text{퐿}_{1}(\text{퐿}_{\text{퓚}}, \text{픐}, \text{픐}_{\text{퓚}}) \quad (7)$$

$(\text{픐}_{1}, \text{픐}_{3})$ Weights and biases of the first convolutional layer, 휎 represents the activation function. Depthwise separable convolutions are used in subsequent layers to reduce the number of parameters while preserving spatial and channel relationships:

$$\text{퐿}_{\text{퓚}}(\text{픐}, \text{픎}) = \text{휎}(\text{퐿}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{퓚}_{\text{퓚}}hN\ \text{표}_{\text{퓚}}\text{퓚}_{\text{퓚}}(\text{퐷}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{퓚}_{\text{퓚}}h, \text{픐}\boxtimes\ \text{픈}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{표}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{픈}2\ \text{퐿}(\text{퐿}_{-1}, \text{픐}_{\text{퓚}}) + \text{픾}_{\text{퓚}}\text{표}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{픐}, \text{픈}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{표}_{\text{퓚}}\text{퓚}_{\text{퓚}}\text{픈}2\ \text{퐿}(\text{퐿}_{-1}, \text{픐}_{3}))) \quad (8)$$

Where, 푾푑 is the weights for depthwise convolution, 푾푝 denotes the Weights for pointwise convolution. This decomposition allows independent spatial filtering (depthwise convolution) and feature mixing (pointwise convolution). Max-pooling is used to reduce the spatial magnitudes and retain salient features:

$$푀_k(푖, 푗) = \max\{푀(푖 + i, 푗 + j)\}, \forall\, i, j \in \{0,1, \ldots\ldots, \quad 푘 - 1\} \tag{9}$$

where k is the pooling kernel size.

Step 3: Attention Module

An attention mechanism is integrated to improve the network's focus on relevant regions of the spectrogram. The channel attention mechanism operates as follows:

1. Global Average Pooling (GAP): The spatial dimensions are averaged to compute a channel descriptor:

$$푧_c = \frac{1}{퐻 \times 푊} \sum_{x=1}^{퐻} \sum_{y=1}^{푊} 푀_c(푖, 푗) \tag{10}$$

where $푧_c$ represents the GAP result for channel c, and H is the height and W is the width of the feature map.

2. Fully Connected Layers: The channel descriptors are passed through fully connected layers,

$$푠_c = 휎(푊_u \cdot 푧_c + 푏_u) \tag{11}$$

where $푊_u, 푏_u$ are weights and biases of the attention module, and σ is the sigmoid activation function.

3. Attention Weighting: The attention scores $푠_c$ are applied to the feature maps:

$$\tilde{푀}_c(푖, 푗) = 푀_c(푖, 푗) \cdot 푠_c \tag{12}$$

Step 4: Multi-scale Feature Fusion Module

Features from multiple layers are combined to utilize both low-level and high-level information:

1. Feature Concatenation: Feature maps from layers $푙_1, 푙_2 \ldots\ldots\ldots 푙_n$ are concatenated along the channel dimension:

$$푀_{푓푢푠푒푑} = 퐶표푛푐푎푡(푀_{푙_1}, 푀_{푙_2}, \ldots\ldots 푀_{푙_n}) \tag{13}$$

where Concat denotes channel-wise concatenation.

2. Feature Aggregation: The concatenated features are further handled using a convolutional layer,

$$푀_{푓푖푛푎푙} = 휎(퐵푁(퐶표푛푣2퐷(푀_{푓푢푠푒푑}, 퐾_푑))) \tag{14}$$

Step 5: Classification Module

The final feature representation $푀_{푓푖푛푎푙}$ is flattened and conceded through fully connected layers for classification.

The extracted features are transformed into class scores:

$$푧_c = 푊_c \cdot 푓_{푓푖푛푎푙} \tag{15}$$

$푊_c, 푏_c$ are weights and biases. The class probabilities are computed using the softmax function

$$푃(푐|푥) = \frac{\exp(z_c)}{\sum_{k=1}^{C} \exp(z_k)} \tag{16}$$

where C determines the total number of classes. The predicted cry type matches to the class with the maximum probability:

$$\hat{푦} = \tag{17}$$

$$푎푟푔푚푎푥_c 푃(푐|푥)$$

Step 6: Performance Evaluation

The model's performance is estimated using key metrics like accuracy, precision, recall, and F1-score.

V.RESULTS AND DISCUSSION

Dataset Description: Donate-a-Cry Dataset

The experiments were carried out on the Donate-a-Cry Dataset, which consists of infant cry recordings collected under various conditions. This dataset contains diverse cry samples categorized into several classes, such as normal, hunger, discomfort, and belly pain. The dataset provides a balanced representation of each class to ensure robust model training and evaluation. Each cry recording was preprocessed to generate Mel-spectrograms, which serve as input features for the deep neural network classifier.

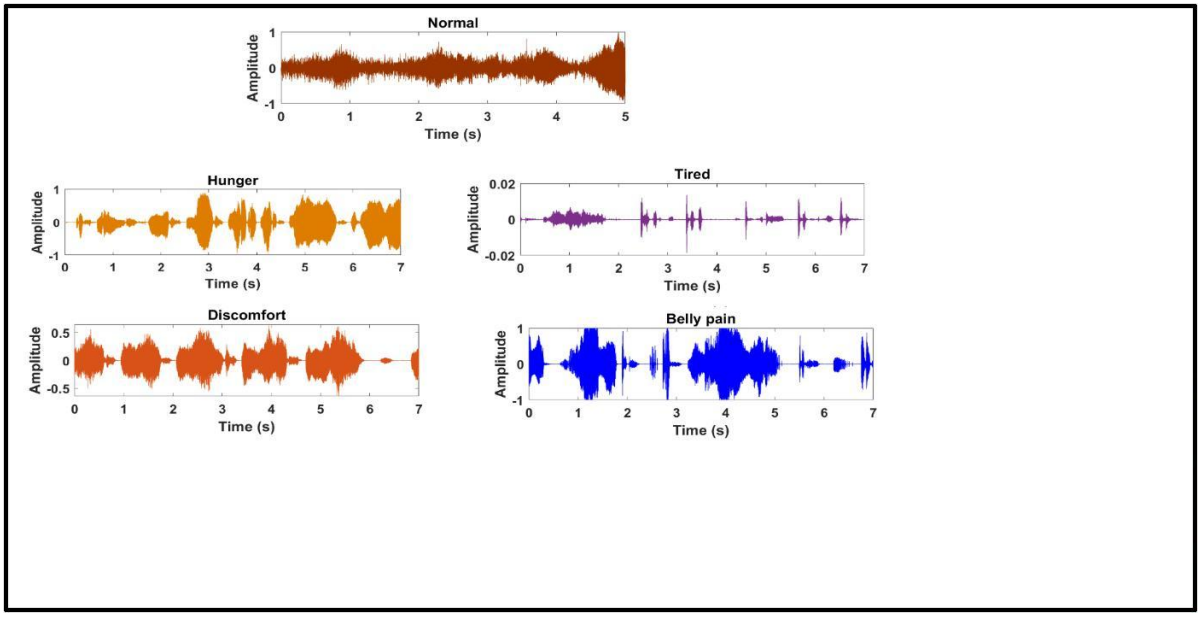

FIG 3 Different infant cry signals

The provided **FIGURE 3** illustrates waveform plots of different types of infant cries. Each observation shows the amplitude variations over time, highlighting distinct patterns for each cry type. The normal cry demonstrates a relatively stable and rhythmic amplitude, whereas the hunger cry shows a more pronounced variation with increased intensity toward the latter part of the signal. The tired cry features periodic bursts of higher amplitude, reflecting fatigue-associated vocalizations. In contrast, the discomfort cry displays irregular patterns with sharp, high-amplitude peaks, indicative of distress. Lastly, the belly pain cry reveals repetitive short bursts with lower overall amplitude, representing the unique characteristics of pain-related cries. These plots underscore the importance of analyzing the temporal and amplitude dynamics for effective cry classification.

Evaluation Metrics

The effectiveness of the proposed method was assessed using widely adopted classification metrics, namely accuracy, precision, recall, and F1-score. These metrics are computed based on the following parameters: True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN).

4.2.1 Accuracy

It is measured as the fraction of total samples that are classified correctly by the model.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (18)$$

4.2.2 Precision

It measures the designed models capability to identify true positive samples while avoiding incorrect positive classifications.

$$\text{Precision} = \frac{TP}{TP + FP} \quad (19)$$

4.2.3 Recall (Sensitivity)

The percentage of true positive cases that the model identifies out of all actual positive cases.

$$\text{Recall} = \frac{TP}{TP + FN} \quad (20)$$

4.2.4 F1-Score

A parameter that combines recall and precision using their harmonic mean, emphasizing the balance between the two.

$$\text{F1} - \text{Score} = \frac{2.Prec \times .Recall}{2.Prec + Recall} \quad (21)$$

The *NeoNet* classifier is chosen due to its ability to efficiently extract, refine, and classify features from Mel-spectrograms while maintaining low computational complexity compared to conventional deep learning models. The combination of attention mechanisms, multiscale feature fusion, and BiLSTM enhances the discrimination of cry types while ensuring interpretability. Moreover, *NeoNet* is optimized for scalability, making it suitable for real-time infant cry classification applications in neonatal healthcare.

Mel- Spectrogram

The Mel-spectrograms obtained for each cry type is represented below in Figure 5. The variations is observed in each cry pattern because of its frequency variations observed in the cry signal.

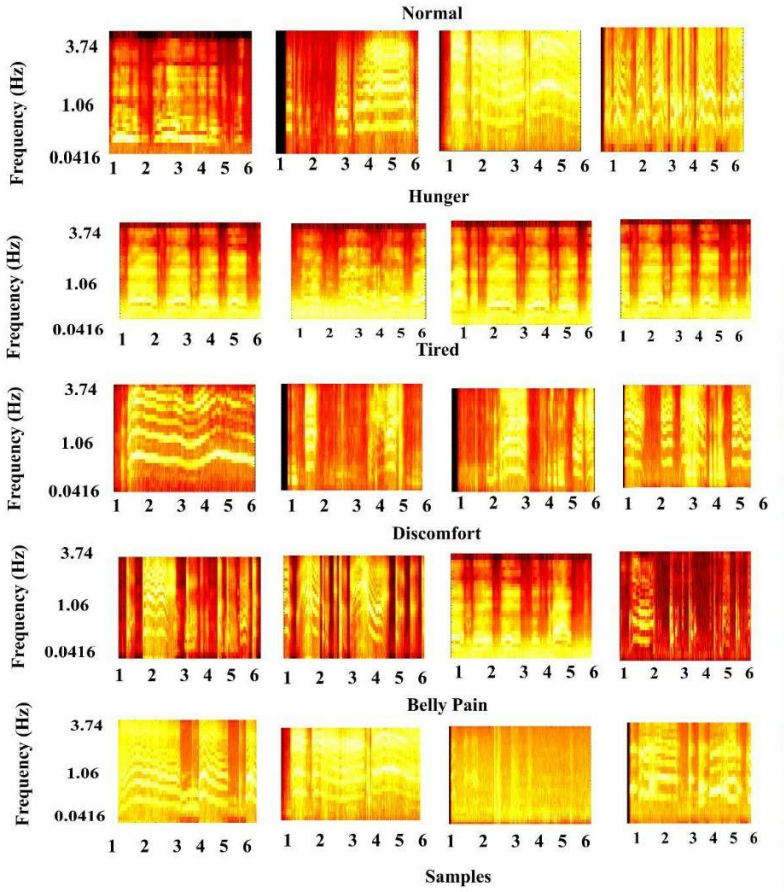

FIG 4 Melspectrograms of different types of cry signal

FIGURE 4 shows the obtained melspectrograms for each cry signal. In this study, mel spectrograms were computed for diverse types of infant cry signals to capture the variations in frequency and time characteristics that distinguish the cries. The infant cries were categorized into various types, such as hunger, pain, and discomfort, based on their distinct acoustic properties. For each cry type, the mel spectrograms revealed significant differences in frequency patterns, with hunger cries displaying lower frequency components and discomfort cries showing higher frequency variations. The temporal evolution of these spectrograms also exhibited unique patterns, with pain cries demonstrating more abrupt and erratic changes compared to the smoother transitions observed in hunger and discomfort cries. These variations in the mel spectrograms serve as a critical feature set for the deep neural network classifier, enabling the effective classification of the different infant cry categories based on their inherent acoustic features.

Performance Comparison Table (Combined Techniques and Models)

Feature Technique + Model	Accuracy	Precision	Recall	F1-Score
WT + ANN	80.5	79.8	80.0	79.9
WT + CNN	83.2	82.5	83.0	82.8
WT + InceptionV3	86.7	86.0	86.5	86.2
WT + Proposed Model	90.3	89.8	90.1	90.0
WPT + ANN	82.6	81.9	82.3	82.1
WPT + CNN	85.4	84.8	85.1	85.0
WPT + InceptionV3	88.9	88.3	88.6	87.2
WPT + Proposed Model	92.5	92.0	92.3	92.2
STFT + ANN	85.1	84.5	85.0	84.7
STFT + CNN	87.8	87.2	87.5	87.4
STFT + InceptionV3	91.0	90.6	90.8	90.7
STFT + Proposed Model	94.2	93.8	94.0	93.9
Spectrogram + ANN	88.3	87.6	88.0	87.8
Spectrogram + CNN	90.9	90.4	90.7	90.5
Spectrogram + InceptionV3	94.3	93.9	94.1	94.0
Spectrogram + Proposed Model	96.5	95.8	96.5	96.1
Mel-Spectrogram + ANN	89.6	89.0	89.4	89.2
Mel-Spectrogram + CNN	92.5	92.0	92.3	92.2
Mel-Spectrogram + InceptionV3	95.0	94.6	94.8	94.7
Mel-Spectrogram + Proposed Model	96.5	95.8	96.5	96.1

TABLE 1 outlines the performance comparison of the diverse classifiers

The performance comparison table presents a detailed analysis of various feature extraction techniques, including WT, WPT, STFT, Spectrograms, and Mel-Spectrograms, paired with different classification models. The analysis includes classical methods such as Convolutional Neural Networks (CNN), Artificial Neural Networks (ANN), and pretrained architectures like InceptionV3, alongside the proposed deep learning model. The following paragraphs provide an in-depth discussion of the findings.Wavelet Transform, being one of the foundational techniques for feature extraction, provides a hierarchical frequency decomposition of the infant cry signals. When paired with ANN, the results show sensible performance, outcomes with an accuracy of 80.5% and an F1- score of 79.9%. This is primarily due to ANN's limited ability to exploit the multi-resolution features of WT. However, incorporating CNN improves the performance to 83.2% accuracy, as CNN captures localized patterns within the WT feature space. The pretrained InceptionV3 model further enhances the performance to 86.7% accuracy by leveraging its deeper convolutional layers to extract more abstract features. Finally, the proposed model achieves the highest accuracy of 90.3% with WT, as its attention mechanism and multi-scale feature fusion optimize the extraction of both global and local temporal-frequency features.

WPT refines WT by providing a more detailed frequency breakdown, yielding higher accuracy across all classifiers. ANN achieves 82.6%, while CNN improves to 85.4%. InceptionV3 reaches 88.9% by effectively leveraging WPT's finer resolution. The proposed model outperforms all, achieving 92.5%, thanks to its ability to extract both local and global features from the enriched frequency decomposition. STFT improves temporal resolution compared to WT and WPT. ANN achieves 85.1%, CNN improves to 87.8%, and InceptionV3 reaches 91.0% with STFT. The proposed model achieves 94.2%, effectively utilizing STFT's time-frequency representation via multi-scale fusion.Spectrograms offer visually rich time-frequency features. ANN achieves 88.3%, CNN improves to 90.9%, and InceptionV3 achieves 94.3%. The proposed model achieves 96.5%, outperforming others by optimizing the extraction of spectrogram features with its advanced architecture. Mel-spectrograms, designed to mimic human auditory perception, show the best results. ANN achieves 89.6%, CNN improves to 92.5%, and InceptionV3 reaches 95.0%. The proposed *NeoNet* classifier achieves state-of-the-art performance at 96.5%, owing to its ability to exploit spectral and temporal patterns comprehensively. The proposed model consistently achieves superior performance, particularly with spectrograms and Mel-spectrograms, highlighting its ability to integrate time-frequency information effectively. This analysis underscores the importance of combining perceptually aligned features like Mel-spectrograms with robust classifiers for optimal infant cry classification.

VI.CONCLUSION

This study presents a novel architecture specifically designed for infant cry classification that combines Mel-spectrogram representations with a custom deep neural network (*NeoNet)* classifier. The Mel-spectrograms effectively capture the temporal and spectral dynamics of infant cries, serving as a robust feature set for classification. NeoNet demonstrated its ability to accurately discriminate between different cry types, achieving superior performance metrics, including precision, recall, accuracy, and F1-score, on publicly available datasets. These results underscore the efficiency of deep learning techniques in enhancing infant care, offering a reliable and interpretable solution for cry classification. The proposed system lays the foundation for developing automatic tools that can support caregivers and medical professionals in recognizing and addressing the needs of infants prompt and effectively. Future research will explore integrating additional cry types and real-time processing capabilities to further broaden the applicability of this framework.

Abstract. The advent of Wireless Sensor Networks (WSN) and proliferation of Internet of Things(IoT) devices has driven the demand for self-sustaining energy solutions, with rectennas emerging as a viable method for harvesting ambient Radio Frequency (RF) energy. This work presents the design and implementation of a compact dual-band microstrip patch antenna optimized for RF energy harvesting in 2.4 GHz band Wi-Fi (Wireless Fidility) and 5G networks. The proposed antenna achieves dual-band functionality by exciting orthogonal modes through a microstrip feed line, while miniaturization is realized by integrating triangular slots into the antenna patch. A modified ground plane enhances bandwidth, ensuring efficient energy capture across the targeted frequency bands. The S11-parameter analysis confirms resonance at -25.67 dB at 2.52 GHz and -15.19 dB at 3.51 GHz, with a gain of 3.54 dB and 4.21 dB, respectively. The Voltage Standing Wave Ratio remains below 1.5 (1.11 at 2.52 GHz and 1.42 at 3.51 GHz), ensuring minimal transmission losses and optimal impedance matching. With its compact form factor and high efficiency, the proposed microstrip patch antenna as a rectenna is well-suited for battery-less IoT sensors, enabling sustainable and autonomous wireless communication.

1. INTRODUCTION

Designing a dual-band microstrip patch antenna as a rectenna for Wireless Sensor Network (WSN) Applications use calls for juggling power management, rectification efficiency, and antenna performance [1]. The main design criteria are picking the right frequency bands, making the antenna design better for dual-band operation, and making sure that Schottky diodes (or any other rectifier diode) and matching networks work well for rectification [2]. Furthermore, including power management and energy storage circuits guarantees that the obtained radio frequency (RF) energy is kept and controlled for usage in WSN devices including Internet of Things (IoT) with energy economies [3].

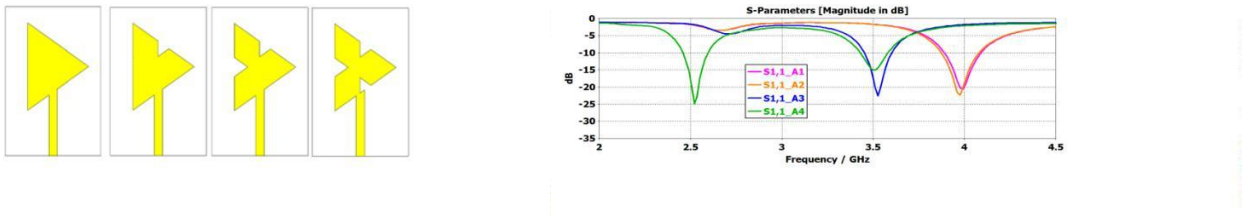
The objective of this work is to develop a small, high-efficiency system able to supply WSN devices with continuous, sustained power without using batteries or outside sources. The IoT has brought in a time when device interoperability and connection become rather important. To guarantee strong communication, this requires the creation of effective antennas able to run across several frequency ranges. Because they can support several communication protocols, dual-band antennas, which can run on two distinct frequency ranges, are especially useful

in WSN applications. Because they can run effectively across several frequency ranges, the dual-band antennas have evolved into essential components of contemporary wireless networks. For uses like IoT, 5G, and WLAN systems, antenna design must take performance, simplicity of fabrication, and compactness as top priorities [4].

This paper suggests a microstrip antenna design that should work at both 2.52 GHz and 3.51 GHz, allowing for dual-band operation with a simple but useful structure. The antenna uses a new triangular patch construction in conjunction with a feedline to achieve dual-band operation while maintaining a small size.

2. LITERATURE REVIEW

Recently, numerous dual-band antenna designs have emerged to meet the increasing demands of wireless communication systems. Particularly because of their flat shape, simplicity of construction, and fit with printed circuit boards, microstrip antennas are under great research interest.

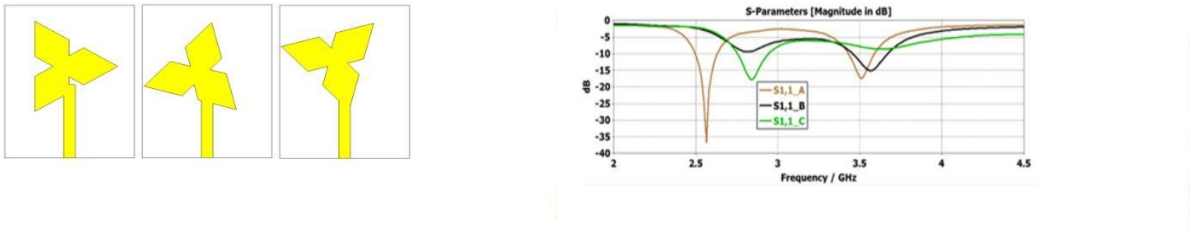


Researchers have looked at a range of geometries, including rectangular, circular, and triangular patches, in an attempt to achieve dual-band or multi-band performance. For WLAN and WiMAX bands, for example, [5] proposed a rectangular slot-loaded patch that showed compactness but required more tuning elements.Using designs inspired by metamaterials, as looked at in [6], has led to better bandwidth and gain for multi-band uses. Still, the complexity of these designs usually rises. Researchers have thoroughly investigated microstrip-line and coaxial-feed systems. As used in [7], microstrip-line feeding helps to match; yet, it requires careful impedance modification. Because of its small form factor and effective radiation characteristics, triangular patch antennas—as detailed in [8]—are excellent for portable electronics.

Dual-band antennas for IoT applications have gained a lot of interest since they can run over different frequency bands, thereby providing alternative communication options. Many publications show new designs for compact dual-band antennas appropriate for IoT devices. One way is to use two adjacent resonance loops in loop-type antennas to give each band its own independent control at 0.92 GHz and 2.45 GHz [9]. One design uses a microstrip antenna that works at 868 MHz and 1.57 GHz for GPS and LoRa IoT, resulting in gains of 3.35 dBi and 5.08 dBi, respectively [10]. Particularly certain designs center on particular IoT contexts or applications, as shown by a small antenna with a total volume of 30 x 10 x 1.6 mm^3 [11] working at 0.9 GHz and 2.45 GHz. Low 5G (n18) and 915-MHz ISM frequencies are used by a flexible dual-band antenna for IoT close to the body [12]. In a different method, PIN diodes [13] are used to switch between dual-band and wideband modes. This makes it possible to design antennas that can work with different frequencies. Some researchers have investigated how numerous communication technologies—including NFC with dual-band UHF/2.45 GHz RFID reader antennas for IoT applications—might be merged [14]. Ultimately, dual-band antennas for IoT applications exhibit many designs and operating frequencies to match various IoT usage scenarios. Often prioritizing simplicity, affordability, and outstanding performance throughout several frequency ranges, these antennas. The variety of designs—including loop-type and microstrip antennas as well as reconfigurable and integrated systems—showcases the continuous inventiveness in this field to satisfy changing needs of IoT technology.

Chen et al. report in [15] the design of a low-profile dual-band planar inverted-F antenna (PIFA) for Internet of Things uses. Excellent radiation performance at both 1.8 GHz and 2.4 GHz comes from this antenna. Its simplicity and low cost help it increase its attractiveness even more. The subject of RF energy collecting technology has advanced significantly recently. Early studies have mostly focused on single-band antennas, which are usually tuned for particular frequency ranges, such as 2.4 GHz or 5.8 GHz. Still, the spread of multi-band communication networks calls for antennas able to efficiently harvest energy from many frequency ranges [16]. With the aim of improving the efficiency of power conversion, several dual-band RF harvesting devices have been suggested, including slot antennas, monopoles, and patch antennas. Meanwhile, we must harmonize the antenna's size, gain, and impedance matching to maximize energy harvesting. In this regard, the suggested design breaks free from size and complexity restrictions and offers competitive dual-band performance suitable for modern wireless devices.

3. ANTENNA DESIGN AND CONFIGURATION



We develop the proposed antenna on an FR4 substrate with a thickness of 1.6 mm and a relative permittivity of 4.4. The radiating patch exhibits a triangular design with extensions optimized for dual-band functionality. We calibrate the feedline to match 50 impedances, ensuring minimal reflection and efficient power transfer.

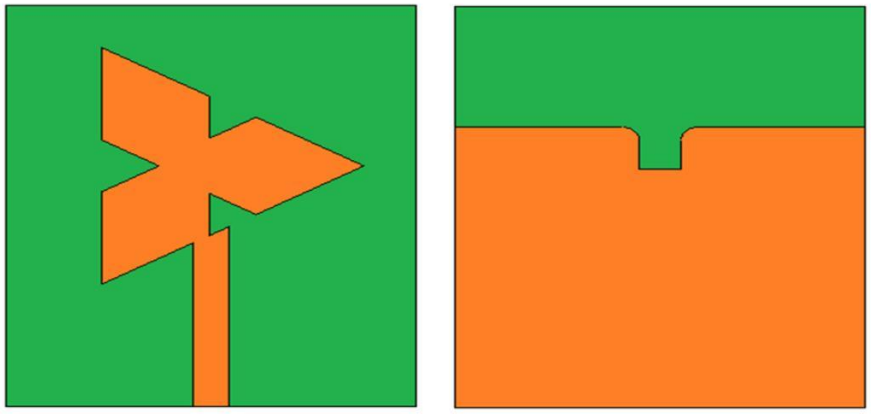
FIGURE 1. (a) Triangular Slot Loading, (b) S11 Optimization for Slot Loading

The dual-band antenna for the collection of RF energy in Wi-Fi and 5G networks has been meticulously designed and executed through several critical phases. Initially designed to facilitate dual-band resonance through the activation of orthogonal modes, a microstrip-fed patch antenna. The efficient transfer of energy and the optimization of impedance matching are achieved through the utilization of a microstrip transmission line. As illustrated by the Fig. 1(a), triangular openings have been incorporated into the patch to facilitate miniaturization while maintaining performance by altering the current distribution to enhance resonance at Wi-Fi and 5G frequencies. Additionally, a partial ground plane has been incorporated to enhance impedance bandwidth, thereby ensuring the efficient collection of RF energy across a wide frequency spectrum.

(a) (b)

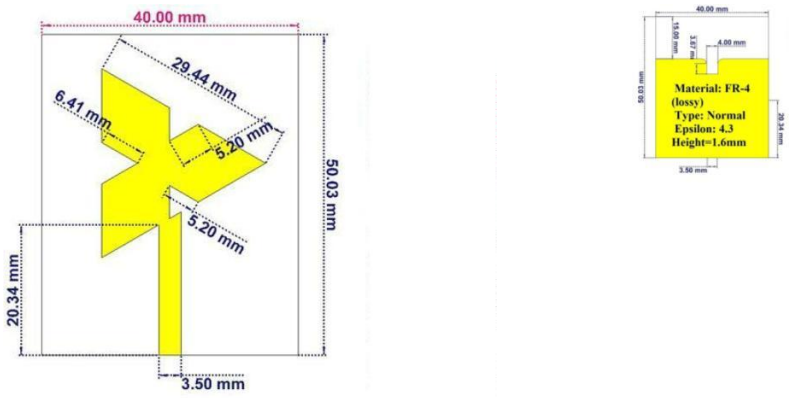
FIGURE 2. (a) Antenna Orientation (b) S11 Optimization for Orientation



The stable dual-band functionality of the final antenna design is achieved through a process of iterative optimization as evidenced by the above illustrations. The S-parameter analysis corroborates a favorable return loss and efficient energy capture at both designated frequencies, thereby affirming the performance as shown by the Fig. 1(b) and 2(b). This methodology ensures that the antenna is compact, efficient, and suitable for wireless energy harvesting applications within modern Wi-Fi and 5G communication networks.

3.1 Radiating Patch

Figure 3(a) shows the radiating part of the antenna. The cross-shaped arrangement implies that the gadget has been tuned for resonance at two different frequencies, enabling dual-band capability. By establishing different resonant paths within a rectangular substrate, the special arrow-shaped geometry creates dual-band resonance. The green backdrop represents the ground plane, also known as the substrate, upon which the antenna rests. A fundamental component of the antenna construction, the ground plane allows the most ideal impedance matching and radiation properties. The ground plane protects and supports the radiating body electrically. Using the asymmetric features of the design, especially the elongated arm on the cross, often changes the response of the antenna to particular frequencies.



3.2 Ground Plane Cutout

Figure 3(b) shows a slot in the ground plane, which could function as part of the resonant structure. People often use these apertures to attain additional resonances or enhance antenna tuning, thereby enhancing dual-band capability. For dual-band operation, a notch or aperture in the ground plane improves coupling and helps to control impedance. With this arrangement, one can use a partial ground plane to improve bandwidth control and impedance matching. One further approach to improve the resonance frequencies of the antenna is the ground slot. The substrate and general configuration define the operating frequencies, bandwidth, and efficiency. A low-loss dielectric substrate could enhance the antenna's performance.

FIGURE 4. (a) Design Parameters of Patch (b) Design Parameters of Slot

3.3 Design Parameters

Compact antennas used in modern wireless systems, including Wi-Fi, mobile phones, and IoT devices, where spatial restrictions demand effective multi-band solutions, feature this kind of design extensively.

- Substrate: FR4 (dielectric constant = 4.4, thickness = 1.6 mm)
- Resonant Frequencies: 2.52 GHz and 3.51 GHz
- Patch Dimensions: as shown in the Figure 4.

4. RESULTS AND DISCUSSION

We used CST Microwave Studio and ADS (Advanced Design System) tools to simulate the antenna. For both frequency ranges, the simulations focus on important characteristics like gain, efficiency, and return loss (S_{11}). The modeling results show that the antenna has a clear resonance at both 2.52 GHz and 3.51 GHz, which means that it has a return loss better than -10 dB at both frequencies.

4.1 Return Loss (S11) Analysis

The S_{11} parameter, shown in Figure 5, reveals resonant frequencies at 2.52 GHz and 3.51 GHz with return losses of -25.67 dB and -15.19 dB, respectively. These findings show excellent frequency band functioning and impedance matching. The S_{11} of the antenna gauges the extent of input power reflection back to the source. Given in decibels (dB), it is derived as:

$$S_{11} = -20 \cdot \log10(|\Gamma|) \quad (1)$$

where Γ is the reflection coefficient.

The antenna reflects all of the input power and does not transmit any when $S_{11} = 0$ dB. Conversely, when S_{11} is very negative that is, less than -10 dB, the antenna reflects only a modest portion of the input power and transfers most of it. Two sudden drops in the S_{11} graph show the antenna's resonance frequencies. The antenna radiates effectively at these spots and is in good alignment with its feeding system.

First Dip (2.52 GHz): The S_{11} is -25.67 dB, indicating that nearly all input power is allocated to the antenna for radiation. This frequency is likely linked to a particular application, such as Wi-Fi (2.4 GHz band) or comparable wireless communication technology.

Second Dip (3.51 GHz): The S_{11} measures -15.19 dB, indicating somewhat increased bounce while maintaining effective performance. This frequency may be compatible with alternative standards, such as enhanced Wi-Fi (5 GHz band harmonics), Bluetooth, or LTE frequency bands.

An S_{11} value of -10 dB or lower, which corresponds to 10% reflected power, is generally regarded as acceptable for the majority of antennas. The antenna can work with two frequencies at the same time, as shown by the plotted S_{11} graph, which shows that both resonance frequencies (2.52 GHz and 3.51 GHz) meet this requirement.

Analyzing the width of the drop at the resonance frequencies can determine the bandwidth associated with each resonance. A narrow dip indicates that the antenna is precisely tuned to a specific frequency (narrowband), while a wider dip implies that it can accommodate slight frequency fluctuations (wideband). Significant declines in the graph suggest the antenna's likely design for narrowband operation at the two indicated frequencies. As you can see from the Resonance Depth graph, the first dip is bigger than the next dip. This means that matching is better at 2.52 GHz compared to 3.51 GHz. This observation suggests that the first band exhibits a higher level of optimization or that the second band incurs slightly greater reflection losses.

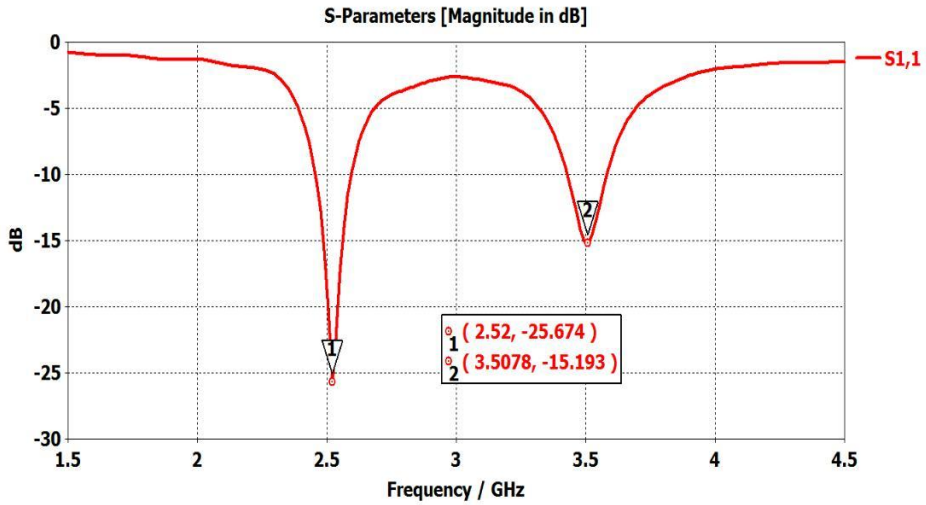

FIGURE 5. S_{11} Graph of Proposed Antenna

The graph shows that the antenna works well at both 2.52 GHz and 3.51 GHz, showing that it has good impedance matching at both frequencies. The antenna's highly tuned design, as evidenced by the abrupt dips, makes it suitable for modern communication systems that require precise frequency operation. Commonly used in wireless technologies, including Wi-Fi (IEEE 802.11b/g/n), Bluetooth, and Zigbee communication, is the first band—2.52 GHz. The excellent S11 performance of the antenna at this frequency makes it efficient for several uses. The second band, 3.51 GHz, is most likely intended for C-band frequency range applications or LTE-Advanced, 5G Sub-6 GHz bands. The antenna can efficiently emit in this range even though it is somewhat less optimized than in the first band.

The modified ground plane influences the current distribution and impedance matching of the antenna, therefore improving the bandwidth. Unlike a conventional microstrip antenna, which frequentlyshows narrowband performance at 2-3%, this design achieves a larger bandwidth (~8-10%) at each resonance. The improved bandwidth assures better signal integrity and manages frequency fluctuations arising from production limitations. From the S_{11} Graph of the Antenna, the first band (2.52 GHz) has a 220 MHz bandwidth fit for Wi-Fi and IoT devices. With a 240 MHz, second band (3.51 GHz) is suitable for 5G and C-band uses. The modified ground plane significantly enhances bandwidth, making the antenna more robust for practical wireless applications.

Figure 6 illustrates a Smith Chart depiction of S11 for the dual-band antenna. The Smith Chart is a valuable instrument for analyzing impedance characteristics over a range of frequencies. It represents the antenna's normalized impedance or reflection coefficient in a polar plot. The curve's center indicates optimal impedance matching (Z=50 Ω, Γ=0). The outer boundary signifies total reflection (|Γ|=1), indicating that no power is transmitted to the antenna, while the curved arcs denote the inductive (+jX) and capacitive (−jX) reactance components of the impedance.

From the Smith Chart following inferences can be made:

4.1.1 1st Resonance (2.52 GHz)

Impedance: Z = (49.14+j5.09) Ω (2)

The real component (R) of the impedance is approximately 50 Ω, which is optimal for matching purposes. Even though it's small, the imaginary part (X) is slightly inductive (+j5.09), which means it has a small inductive reactance

and suggests effective resonance. This point is near the chart's center, as shown in the Smith chart, confirming excellent matching.

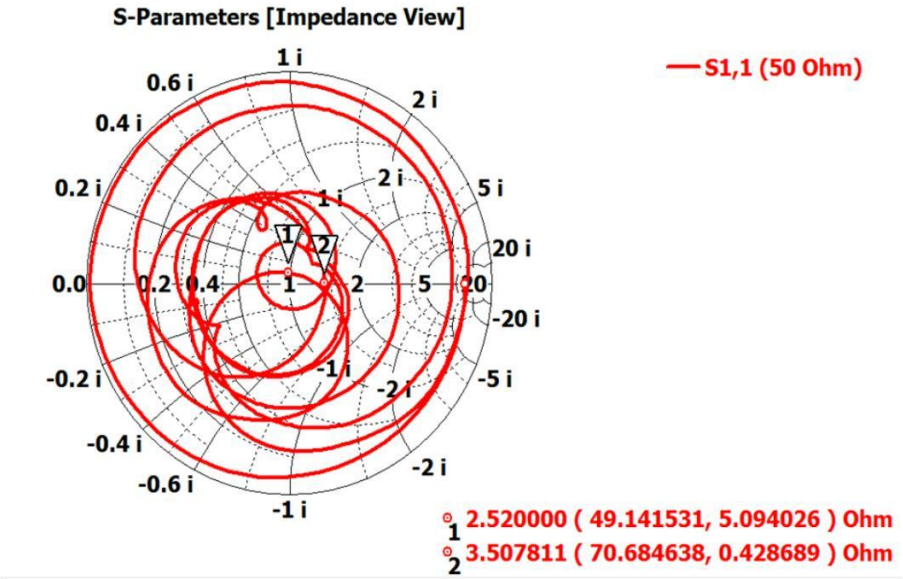

FIGURE 6. Smith Chart representation of S_{11} Parameters

4.1.2 2nd Resonance (3.51 GHz)

Impedance: Z = (70.68+j0.43) Ω (3)

In this case, the imaginary part (X) is almost zero, which means there is almost no reactance and confirms resonance even though the real part (R) is higher than 50 Ω. Compared to the first resonance, this location is slightly further from the center, indicating that this band has a somewhat higher reflection loss.

A look at the S_{11} figure shows that the red line shows the normalized impedance trajectory over the frequency range of 1.5 GHz to 4.5 GHz. At frequencies that aren't resonance, the impedance is very far from the center, showing higher reactance (either inductive or capacitive) and not enough matching. At the resonant frequencies of 2.52 GHz and 3.51 GHz, the impedance loops exhibit convergence toward the center, indicating enhanced matching and efficient energy transmission. The Smith Chart confirms that the antenna achieves optimal matching at two distinct frequencies, therebydesignating it as an effective dual-band antenna. The 2.52 GHz spectrum exhibits enhanced tuning capabilities, likely targeting critical applications including Wi-Fi. The 3.51 GHz range exhibits slightly lower optimization but is still suitable for advanced communication systems, including LTE and 5G Sub-6 GHz.

4.2 Voltage Standing Wave Ratio (VSWR)

The VSWR values in Fig. 7 are 1.11 at 2.52 GHz and 1.42 at 3.51 GHz. This proves that the power is delivered efficiently and there are low reflection losses in the working frequency ranges.

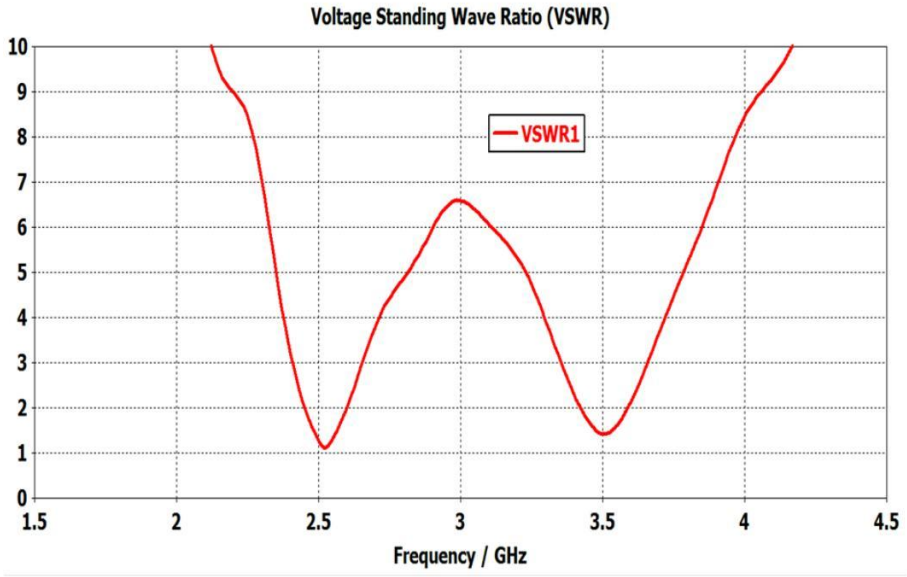

FIGURE 7. VSWR of Dual Band Antenna

The Voltage Standing Wave Ratio (VSWR) is a measure of how effectively radio-frequency power is transmitted from the feedline into the antenna. It is derived from the reflection coefficient (Γ) and is expressed as:

$$VSWR = 1+|\Gamma| / 1-|\Gamma| \quad (4)$$

Where Γ is the reflection coefficient and is related to S11 as:

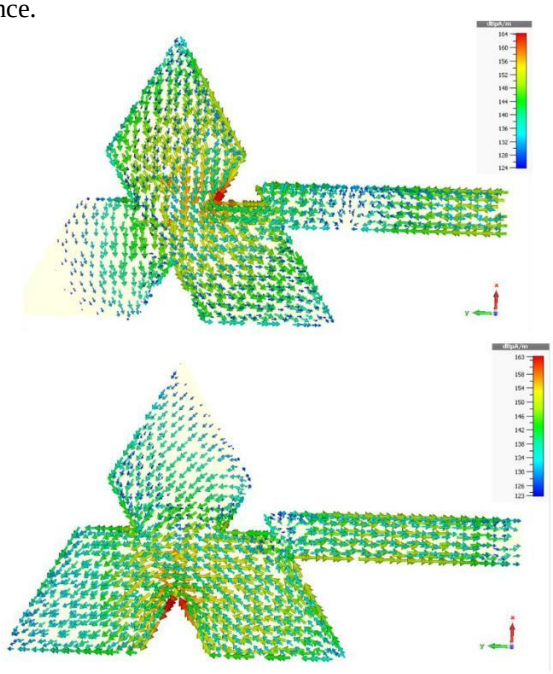
$$|\Gamma| = 10\ S_{11} / 20 \quad (5)$$

A VSWR, that is close to 1 means that the antenna is almost perfectly matched and that there is almost no reflected power. Typically, most RF systems tolerate a VSWR of under 2. When the resonant frequencies reach 2.52 GHz and 3.51 GHz, which are also the places where the reflection coefficient is lowest, the VSWR should go down. When we exceed certain frequencies, the VSWR increases, leading to a decrease in matching efficiency and an increase in reflected power.

4.3 Surface Current Distribution

Figure 8 shows the active radiating zones for each band by showing how the surface currents are spread out at the two resonant frequencies. The currents exhibit concentration around the feedline and patch boundaries at a frequency

of 2.52 GHz. In contrast, at 3.51 GHz, the distribution extends to additional areas of the structure, thereby confirming the dual-band performance.



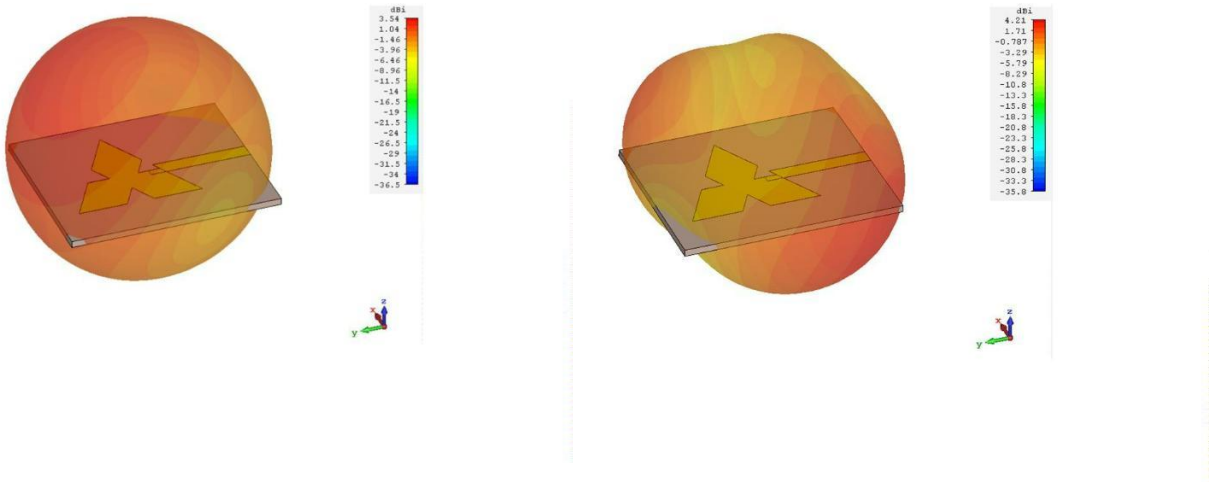


FIGURE 8. Surface Current Distributions of the Antenna

The color gradient indicates the intensity of the currents, with red representing areas of high current density and blue indicating areas of low current density. At the first resonance (2.52 GHz), the surface current is concentrated near the feedline and certain edges of the radiating structure. This shows that there is a strong energy coupling at the lower band. Additionally, the current shift at the second resonance (3.51 GHz) demonstrates a change in the effective current path length to other parts of the radiating structure for the higher band. The antenna exhibits dual-band behavior, with distinct portions radiating at specific frequencies, as evidenced by the current distributions observed. The measured patterns indicate effective impedance matching and efficient energy radiation, as the currents are distributed within resonance-optimized areas.

4.4 Radiation Patterns and Gain

The antenna's radiation patterns, depicted in Figure 9, exhibit near omnidirectionality at 2.52 GHz and slight directionality at 3.51 GHz. The simulated gain values for the lower and upper frequencies are 3.54 dBi and 4.21 dBi, respectively, which indicates efficient radiation performance.

A 3D radiation pattern illustrates the gain, with color intensity representing dBi. The blue regions indicate minimal improvement, whereas the yellow and red portions signify greater gain. The antenna has a pattern that is somewhat omnidirectional and a gain of about 4.21 dBi at 3.51 GHz, which means that it has slightly better gain and directional characteristics. At 2.52 GHz, the gain values are about 3.54 dBi. The elevated gains signify superior performance regarding signal strength, while the lobes denote the primary radiation directions, aligning with the antenna's dual-band operational purpose. The patterns demonstrate that the antenna provides efficient radiation across both bands.

(a) (b)

FIGURE 9. (a) Radiation Gain Pattern at 2.52 GHz (b) Radiation Gain Pattern at 3.51 GHz

4.5 Summary

Narrowband operation is achievable due to the design of the antenna, and there are multiple applications where it outperforms wideband systems. We can modify resonances or enhance bandwidth by making adjustments to slot size, radiating element design, and substrate material.

1. Dual-Band Performance: The surface current distribution and the radiation patterns clearly demonstrate dual-band activity at 2.52 GHz and 3.51 GHz. The radiation mechanisms differ for each band.
2. Gain Efficiency: The typical gain values for small printed antennas render this design appropriate for applications requiring moderate directional gains.
3. Design Validation: The matching of current distribution, gain patterns, and resonant frequencies confirms the antenna's design efficiency for the specified frequency ranges.

5. CONCLUSION

We have finalized the design and analysis of a dual-band microstrip patch antenna operating at frequencies of 2.52 GHz and 3.51 GHz. When used in wireless applications, the antenna works best because it has low VSWR, little return loss, and good gain. We have scheduled the fabrication and experimental validation of the simulated results. To improve second band matching at 3.51 GHz, it is advisable to incorporate a matching network or modify the ground plane design to achieve an impedance of 50 Ω. Adjusting the radiating patch through slot loading or multi-resonant structures enhances the operational bandwidth. Utilizing advanced methodologies, including metamaterials and high-ε substrates, enhances compactness while maintaining performance integrity. This antenna is optimized for smart devices utilizing Wi-Fi (2.4 GHz) and 5G (3.5 GHz) connections, as well as IoT devices that operate across multiple bands. It is also suitable for wearables and small-form-factor devices requiring compact, dual-band configurations.

***Abstract*--**This paper examines algae's potential as a sustainable and renewable resource for the manufacture of biofuel, highlighting how it can help meet the world's energy needs while reducing environmental impacts. The biofuels produced from algae are beneficial because they offer carbon-neutral and environmental friendly substitutes for fossil fuels, with the added advantage of not competing with food crops and arable land. Therefore, the potential of macroalgae and microalgae in the production of biofuels is investigated, with an emphasis on important biofuels like biodiesel, bioethanol, bioelectricity and biogas. Lipid extraction and stress-induced biochemical alterations are two significant elements that impact the viability of algae-based biofuels. Along with important farming methods, pretreatment strategies, and conversion procedures that can improve the output and effectiveness of biofuels are covered in this work. Additionally, a review of Internet of Things (IoT) technology integration to optimize industrial processes is included in this paper. This survey addresses the scalability, energy efficiency, and economic feasibility issues while looking more closely at sophisticated production techniques including open pond cultures and photobioreactors. It identifies the critical research and technological advancements required to close the gap preventing the large-scale production of algae-based biofuels in the direction of a more environmentally sustainable energy future.

Keywords: Algae, Biofuels, Biodiesel, Lipid extraction, Sustainability

I.INTRODUCTION

Fossil fuels, the foundation of current energy systems, are finite resources that are rapidly consumed due to continuous usage [1]. Their extraction and utilization significantly contribute to climate change, greenhouse gas emissions, and environmental destruction. There is a pressing need for renewable and eco-friendly energy sources due to rising global energy consumption and the adverse impacts of fossil fuels on the environment. First-generation biofuels, often referred to as crop-based fuels, include crops such as maize, sugarcane, soybeans, and oil palm. These crops are processed to generate fuels like bioethanol and biodiesel, serving as alternatives to traditional fossil fuels. Bioethanol is obtained through the fermentation of sugar or starch-rich crops, while biodiesel is produced from the transesterification of soybeans and palm oil [5]. However, concerns regarding food security, land-use changes, and environmental sustainability arise from utilizing food crops for fuel. Large-scale cultivation of biofuel crops can lead to deforestation, biodiversity loss, and water resource depletion.To address these challenges, second-generation biofuels derived from non-food biomass, such as agricultural residues and energy crops, are being developed as more sustainable alternatives. They utilize lignocellulosic materials found in plant cell walls [5]. The production process involves breaking down the tough lignocellulosic structure using pretreatment methods and enzymatic hydrolysis to release fermentable sugars for biofuel production. However, challenges such as high production costs and the complexity of biomass processing must be addressed for large-scale commercial viability.Algae present a promising alternative for biofuel production, offering numerous advantages. Algae-based biofuels are carbon-neutral, as they consume carbon dioxide during growth, effectively offsetting emissions during combustion [12]. Algae do not compete

with food supplies or arable land, as they can grow in non-arable areas, including saline water, waste water, and desert regions, reducing pressure on fertile land and fresh water resources [13][11]. Compared to traditional oil-producing crops, algae can yield between 20,000 to 80,000 litres per acre per year, an output that is 7–31 times more. Some species can make up to 50% of their body weight in oil [11]. Algal biomass demonstrates high energy potential for instance, Chlorella vulgaris biomass has achieved a calorific value of 3000–3500 kcal/kg, and when blended with coal, the calorific values reached 4200 to 5300 kcal/kg [17]. Algae have diverse applications, including the production of dietary supplements, pharmaceuticals, biofuels, and animal feed.Currently, the two basic techniques used for algae production are closed photobioreactors and open pond systems. Open pond systems, such as raceway ponds, are inexpensive to establish and are suited for industrial-scale production under natural light. However, they face challenges like water loss by evaporation, inefficient light uptake, and contamination by undesired species. In contrast, closed photobioreactors are controlled environments where factors affecting algal growth, such as temperature, light, and nutrient supply, are manipulated. While effective in minimizing contamination, their scalability is impacted by high construction and operational costs.

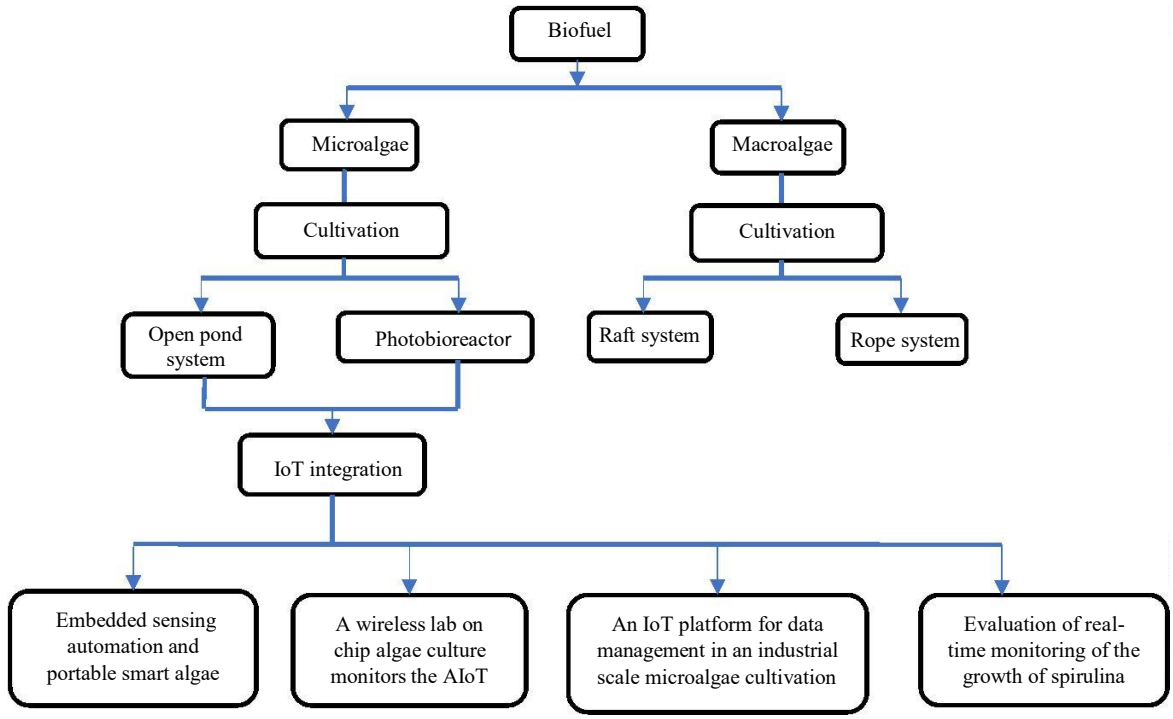

Fig 1: Algae cultivation methods

The manufacture of biofuel from algae is a new technology that researchers are exploring to meet the increasing energy demand. This paper will present various types of algae used in biofuel production and the steps involved in their conversion. Additionally, it will discuss crucial factors imperative to the production and productivity of algae, with a particular emphasis on cultivation methods. The effect of IoT in microalgae farming and recent research on optimization techniques for the culture environment will be explored in subsequent sections.

Microalgae and Macroalgae

Microalgae are single-celled organisms that thrive in diverse environments, including salt water, waste water, and fresh water, making their cultivation more versatile. The production of biofuels relies on lipids, and microalgae are particularly advantageous due to their ability to rapidly grow and produce high lipid yields. These microscopic algae convert sunlight, carbon dioxide, and nutrients into biomass and energy-rich lipids, which makes them an ideal feedstock for biofuel production. They can thrive in poor soils and a range of aquatic environments, with freshwater required only occasionally. Their rapid growth rates and high yield per unit area significantly outperform traditional biofuel crops like corn and soybeans. Biohydrogen and biodiesel derived from algae can reduce carbon emissions and play a key role in advancing the global transition to cleaner energy systems. Therefore, emphasizing research and investment in algal biofuels is essential for achieving

energy security, promoting environmental sustainability, and addressing the urgent energy challenges of our time.Macroalgae, or seaweeds, are multicellular algae found in marine environments. They are typically harvested from natural habitats or cultivated in offshore farms. Unlike microalgae, macroalgae contain carbohydrates such as cellulose, alginate, and laminarin, making them suitable for bioethanol and biogas production. After harvesting, the macroalgae biomass is pretreated to break down complex carbohydrates into fermentable sugars, which are then fermented by microorganisms to produce bioethanol. Additionally, anaerobic digestion of macroalgae generates biogas, primarily methane, which can be upgraded into bio-compressed natural gas (bio-CNG).There are three main categories of algae: green algae (Chlorophyta), red algae (Rhodophyta), and brown algae (Phaeophyta). Unlike land-based crops, macroalgae are cultivated in aquatic environments, eliminating the need for arable land or freshwater, making them eco-friendly sources for biofuel production. Additionally, their rapid growth, high biomass content, and abundance of carbohydrates, lipids, and other valuable compounds enhance their appeal for energy production. However, the use of macroalgae for biofuels faces several challenges, including high production costs, the need for large-scale infrastructure, and technological bottlenecks in processing. The cultivation and harvesting processes require significant investment in technology and labour, while more advanced conversion methods are needed for efficient biomass production. Moreover, the cyclic nature of macroalgae's growth and composition can lead to inconsistent biomass supply and quality, which poses a challenge to large-scale biofuel production.Despite these challenges, macroalgae offer significant environmental and economic benefits. Their cultivation does not require arable land needed for food crops, and they absorb large amounts of carbon dioxide from the atmosphere. Additionally, macroalgae-based biofuels could enhance marine biodiversity by providing habitats for various marine organisms in cultivation farms. Ongoing research in genetic engineering, advanced cultivation systems, and innovative conversion technologies aims to improve the efficiency of biofuel production from macroalgae.

Cultivation techniques

Macroalgae tend to have lower lipid content compared to microalgae but are rich in carbohydrate content, making them ideal for bioethanol and biogas production through fermentation or anaerobic digestion. They can be wild-harvested or cultivated in marine farms, which may require larger land or sea areas. While macroalgae grow more slowly and yield less per unit area compared to microalgae, they are more robust and less prone to contamination. Microalgae, on the other hand, offer a higher yield per unit area and grow faster, making them ideal for lipid-based biofuels. However, they are more susceptible to contamination. Both macroalgae and microalgae have distinct advantages for biofuel production: microalgae are best suited for lipid-based fuels, while macroalgae are more suitable for carbohydrate-based fuels and other value-added products. Due to their different biological structures and metabolic processes, distinct cultivation methods are required for microalgae and macroalgae.

Open Pond Systems

An open pond system is a reservoir or an artificial atmosphere that consists of shallow ponds or tanks or circular ponds or a raceway pond used for the cultivation of microalgae [5]. Algae such as *Spirulina* and *Chlorella* are commonly cultivated in raceway ponds, which can be considered the most popular method in the commercial sector. These ponds have a mechanism to mix the water with the microalgae and also is exposed to air during the growth period of algae. However, this can also be the main challenge for the cultivation of algae to maintain stability of system to ensure high biomass production [3].Additionally, there is always a chance that oxygen may become accumulated, decreasing the overall photosynthesis efficiency. Furthermore, microbial contamination or some unwanted species can inhibit the proliferation of algae. Open pond systems are relatively simple to establish up front, however, they cost a lot more to operate mainly because flocculation, centrifugation, or filtration are typically required for harvest. Maintaining the fertilizers, cleaning, and finding how to lower down costs of production are some of the issues mentioned above. Most of the energy utilized by the system is needed solely for pumping and purging CO2.

Photobioreactors (PBR)

Photobioreactors (PBR) are a controlled system designed to optimize light absorption, CO2 fixation, and nutrient transfer for microalgae cultivation. There are various types of photobioreactors, including tubular, flat-plate, and helical designs. PBRs offer several advantages, such as high photosynthetic efficiency, ease of cleaning, high biomass production, and minimal hydrodynamic stress on algal cells [5]. They also prevent contamination by offering a closed environment and reducing oxygen buildup, which is a common issue in open ponds. However, PBRs have significant challenges, including high construction and operational costs [12]. The

need for artificial light sources (like LED or fluorescent lamps), CO2 supply, and complex designs increases the overall cost of this system. While the volumetric biomass productivity in PBRs can be up to 8 times higher than that in open ponds, the costs are a major barrier. Additionally, issues like algae growth on walls, difficulties in scaling up, and the need for a cooling system complicate PBR-based cultivation.Both open pond systems and photobioreactors offer distinct advantages and face unique challenges. Open ponds are cost-effective for large-scale cultivation, especially when low-cost media can be used, but they face contamination and management issues. Photobioreactors, while offering higher biomass productivity and reduced contamination risks, come with significant costs and operational challenges. The choice between these systems depends on the specific needs, available resources, and scale of the algae cultivation operation.On the other hand, cultivation of macroalgae may take place through both natural and artificial means. Different techniques have been employed for different purposes in enhancing growth and productivity. Macroalgae thrive on coastal coasts, where high intensities of sunlight can be harnessed, and can absorb nutrients in seawater; during photosynthesis, carbon dioxide is also exploited. The nature of such areas, typically under tidal movement dynamics with nutrients, ensures high macroalgae growth with very minimal interference. While artificial cultivation is practiced in farms such as aquaculture, especially those built for enhancing macroalgae production. Such farms may be built along shorelines, estuaries, or even in the open sea depending on the species and the intended purpose. The methods used for maximum productivity include long-line systems, floating nets, and suspended rope and raft structures.

Raft system

In the raft system, a floating frame—typically made of bamboo, plastic, or wood—provides a designated space for macroalgae cultivation. The frame is anchored to the seabed using weights to prevent it from drifting, ensuring that it remains in place even in the face of wave forces. The design of the frame is built to withstand wave strength, keeping the cultivation within the desired location. To promote efficient growth, a shallow and sheltered coastal area is ideal, as it offers a stable environment for the macroalgae. Additionally, this system is flexible, making it easy to relocate the frame if necessary.

Rope system

In the rope system, ropes are suspended both vertically and horizontally to create a substrate where macroalgae can attach and grow. The algae may be manually tied to the ropes or allowed to naturally settle on them. These synthetic ropes are anchored to the seabed to maintain the proper depth, ensuring the algae receives adequate sunlight and nutrients. This system is simple, cost-effective, and provides a larger surface area for cultivation compared to the raft system. However, it requires regular maintenance to remove fouling organisms or epiphytes and prevent overcrowding.The selection of an appropriate site for macroalgae cultivation is a crucial factor for achieving high yields and sustainable production. Key factors include adequate sun exposure, presence of nitrogen and phosphorus nutrients dissolved in the surrounding water and flow of water to ensure nutrient availability and prevent stagnation. Additionally, maintaining appropriate salinity is essential, as high or low levels can impair growth and the quality of biomass produced.

Biofuel Products from Microalgae and Macroalgae Harvesting

Both microalgae and macroalgae are renewable resources with the potential to produce various types of biofuels. Microalgae are primarily used as feedstock for the biodiesel industry due to their high lipid and triacyl glyceride (TAG) content [14]. TAGs are energy-storing substances that can be converted to biodiesel through transesterification and play an important role in β-oxidation, for fatty acids mobilization during stress conditions [18]. When lipids and methanol are combined in a 1:9 ratio, the resulting biodiesel contains fatty acid methyl esters (FAME), with glycerol as a byproduct. The composition of TAGs influences characteristics such as oxidative stability and cold flow properties. Genetic and biochemical enhancements in microalgae aim to increase oleic acid levels while minimizing saturated and polyunsaturated fatty acids to optimize biodiesel quality. Microalgae commonly produce lipids in response to stressors, such as nutrient starvation and changes in light and temperature.

Types of algae	Name of the algae	Cultivation method	Advantages	Drawbacks
Microalgae	Chlorella vulgaris[3][14]	Photobioreactor	Controlled environment and higher productivity	Scaling up can be complex due to light penetration issue
	Spirulina (Arthrospira)[4]	Open System	Reduced contamination risk; easier to cultivate. (can survive extreme alkaline exposure)	Can be affected by temperature fluctuations
	Dunaliella salina[14]	Open System	Tolerates high salinity, which minimizes contamination risk in open systems	Requires large amount of water
	Haematococcus pluvialis[32]	Photobioreactor	Requires controlled conditions to induce astaxanthin production and avoid contamination.	High cost maintenance and require two stage cultivation
	Scenedesmus[3][14]	Open System	Can tolerate varying environmental conditions;	Prone to contamination and difficult to produce constant quality biomass
Macroalgae	Kappaphycus alvarezii (red algae) [30]	Rope System	Provides light and water movement, reduces fouling, and prevents sinking.	Can break in strong currents
	Gracilaria spp. (red algae)[33]	Raft System	Deeper water cultivation, reduces competition with bottom-dwelling organisms, and improves yield.	Unstable in rough waters and prone to biofouling
	Eucheuma denticulatum (red algae)[31]	Rope System	Supports delicate thallus structure, enhances nutrient uptake, and facilitates easy harvesting.	Vulnerable to parasite growth

	Saccharina japonica (brown algae)[14]	Rope System	Stability in high-energy environments, ensures vertical growth, and optimizes exposure to nutrients.	Labor-intensive setup
	Ulva spp. (green algae)[14]	Raft System	Prevents overcrowding, allows for floating cultivation in nutrient-rich areas, and minimizes substrate issues.	Require frequent repositioning due to tides

Table 1: List of species of algae and the system used to cultivate each specie

In addition to lipids, carbohydrates in microalgae serve as significant energy storage source, making them suitable for bioethanol and biohydrogen production. Various pretreatment methods, including physical, chemical, or enzymatic treatments, can hydrolyse carbohydrates into fermentable sugars. For instance, enzymes like alpha-amylase and glucoamylase break down starch into fermentable sugars. While this method has drawbacks, such as high energy inputs and carbon dioxide demand, lipid-extracted algae, like Chlorococum sp., can undergo further processing for ethanol production with yields up to 76% of the theoretical maximum. Some microalgae species, such as Chlorella vulgaris, with growth rates of 20–30 g dry biomass/m^2/day and a starch content of 37%, can achieve up to a 65% ethanol conversion rate[20].Macroalgae, rich in carbohydrates, are ideal for bioethanol and biogas production. Through chemical or enzymatic hydrolysis, brown algae, which contain high levels of polysaccharides, can be broken down into simple sugars. Microorganisms, such as yeast, ferment these sugars to produce ethanol. Although macroalgae have lower lipid content than microalgae, transesterification can still convert these lipids into biodiesel. Additionally, anaerobic digestion, where microorganisms break down organic matter in the absence of oxygen to produce methane-rich biogas, is another method for utilizing macroalgae. Pretreatment techniques involving thermal, chemical, and enzymatic treatments increase the digestibility of macroalgae, thereby enhancing biogas output. This biogas can be used as purified fuel for cars, heating, or power generation.They are typically harvested mechanically by larger companies or hand-harvested by smaller-scale businesses. Some species are harvested using conveyor belts and trawl nets. After collection, macroalgae undergo cleaning to remove residual debris, sand, and shells. The carbohydrate-rich macroalgae biomass is ideal for producing bioethanol and biogas, while microalgae are suitable for lipid production for biodiesel. To maximize the potential of both microalgae and macroalgae as sustainable biofuels, it is essential to combine advanced harvesting practices, efficient pretreatment strategies, and innovative processing technologies. Overcoming technological and financial barriers will be crucial for their widespread adoption as renewable energy sources.

Lipids

Lipid formation is the primary driver of bio-algae fuel production, as it is a key component in determining biofuel yield [2][27]. Various growth techniques are employed to promote lipid accumulation in different microalgae species. As organic compounds, lipids are important for signalling, maintaining structural integrity, and storing energy in cells. Effective lipid extraction is required to optimize generation, given that lipids store significant biological energy.Microalgae produce biomass and lipids through photosynthesis. The lipids produced can be categorized into two major types: polar and non-polar lipids. Non-polar lipids serve as the primary energy reserves of the cell, while polar lipids provide structural support to cellular membranes. However, despite their natural lipid content, microalgae often struggle to produce sufficient amounts of biofuel on a large scale. Therefore, strategic interventions are required to optimize biofuel yield while enhancing the lipid accumulation process.

Factors Affecting Lipid Production

Several factors are essential for the photosynthesis process in algae, including light, nutrients, temperature, stress conditions, and CO2 availability. Temperature significantly affects algal growth and metabolic activity [1]. The optimal temperature range for algal development is between 20 to 40 degrees Celsius [15], although this can vary by species. Higher temperatures tend to promote fatty acid production [2], while lower temperatures aid in synthesizing unsaturated fatty acids. Fluctuations outside the optimal range can negatively impact growth and lipid production.Light is also crucial for algal growth. Algae rely on photosynthesis to generate energy, and maintaining a balance between light and dark sessions is essential for maximum output. It is not only the continuous exposure that is to be maintained but there should be a balance between light and dark sessions to produce maximum output. When the shift from dark to light session is done, algae recover rapidly, with Chlorophyll-a content and cell density rising quickly [16]. For example, Chlorella develops increased biomass production under continuous light exposure with intensities of 200 to 750 $\mu mol\ m^{-2}\ s^{-1}$. However, excessive light can lead to photoinhibition, diminishing the ability to convert light into biomass. Light intensity and wavelength significantly affect algal growth, with studies indicating that red and blue light can enhance development [4][19].Higher concentrations of CO2 and maintaining dissolved oxygen levels above 5 mg/L [26] boost lipid content. However, excessive light and CO2 can lead to adverse effects, such as medium acidification and metabolic disruption. Stress conditions, such as nutrient limitations, salinity variations, and heavy metal stress, play a pivotal role in boosting lipid extraction. Maintaining a balance between stress and growth conditions is essential for commercializing bio-algal fuel. Insights into the effects of each stress factor are necessary to determine the balance that ensures maximum results. Heavy metals like iron, magnesium, and calcium can be tolerated and utilized by microalgae to boost lipid concentration, but excessive reactive oxygen species can cause damage. Metallic nanoparticles, like silica nanoparticles, can enhance CO2 absorption by improving gas-liquid mass transfer, ultimately contributing to lipid productivity.Salt stress is another effective technique for increasing lipid productivity. Variations in salinity alter osmotic pressure, leading to shifts in microalgal metabolism that change fatty acid composition and lipid productivity rates.

Effect of IoT in Algae Cultivation

To maintain high operational efficiency, Internet of Things (IoT) technology plays a significant role in decision-making, automation, real-time sensing, and data transfer [7][27]. Its influence spans various stages, including sensor deployment, integration with bioreactors, and real-time data analytics. Sensors are primarily used for continuous monitoring of quantities like pH, salinity, temperature, and nutrient composition levels [6]. Fluorescence sensors can detect photosynthetic activity, while biosensors identify electrochemical signals from harmful algae or components that may lead to contamination. Data acquisition is done by the multi-wavelength diode-based system, which can be used in open and closed cultivation systems. These automated systems require minimal intervention compared to traditional offline systems, which are often labour-intensive and time-consuming.The process of data collection can be automated by combining IoT systems with photobioreactors. For instance, the data collected from the sensor is transmitted to an IoT application, where the system analyses the data and recommends favourable parameters [7]. Such systems are called Decision support systems (DSS) [22]. The advancements can be made in such a manner that the system responds with the action to optimize the values to get maximum yield.Various machine learning algorithms can be used to analyse the real-time data and conclude the trends in the growth projection, making sure to know the loopholes for the challenges like cultivation environment fluctuations or depletion of CO2 or other required nutrients. The non-invasive approach by automotive flow cytometry checks the cell quality in terms of contamination without the need to ink the cell. The operations to maintain the environment for cultivation can be kept in check by setting up function-specific robots to check parameters like salinity, temperature, light intensity, etc. Apart from all the mentioned possibilities of IoT contribution in the upstream processing, the downstream process can also make use of IoT to optimize the process of producing biofuel from algal biomass[28]. Biosensors can be used to detect the toxins in the system with sensors that can sense electro chemicals. Even at the molecular stage, sandwich hybridization can use species-specific DNA probes to find harmful algae or pollutants. IoT can also engage with automated harvesting and collection processes of masses i.e. diving the biomass from the cultivation medium[29]. The automated systems will be notified when the concentration reaches to desired values and initiate the process of collecting thus preventing over growth of algae. IoT-enabled algae cultivation systems are vulnerable to various cyber-attacks, such as jamming, tampering, and relay attacks, which can compromise sensor data and affect

cultivation outcomes [21].Thus, IOT can play a crucial role in maximizing the productivity of photobioreactors, regular check of cell viability, response and decision support systems, and real-time analysis of data with regular system checks results in efficient, smart way of production of biofuel production.

II.Methods for optimising Algae cultivation

Embedded sensing automation and portable smart algae monitor

The automated multiport smart algae monitor provides a portable, cost-effective monitoring system that addresses limitations of traditional water analysis techniques [8]. This method incorporates microfluidic channels, lens-less imaging, and a deep neural network (DNN) that surpasses the need for traditional, huge equipment that requires human operations. The microfluidic channel serves as a setup for algae sample collection and flow control, reducing maintenance cost which ensures effective imaging and analysis. The combination of a blue LED light source and a CMOS imaging sensor collects holographic images of algae and this is the lens-less imaging system that offers alternatives to conventional microscopes. The implementation of the feature and weight dual asymmetric quantization (FWDAQ) algorithm decreases computational complexity and hardware cost. This system employs FPGA for fast DNN segmentation tasks and a 7-inch user-friendly display to present images, segmentation results, and outputs, enabling real-time result visualization. The whole system is structured in an 11*11*17.5cm cuboid, making it compact and portable. In terms of setup and process, algae samples are moved towards the microfluidic channels with the help of miniature pumps, and the flow rate is controlled for accurate image acquisition.

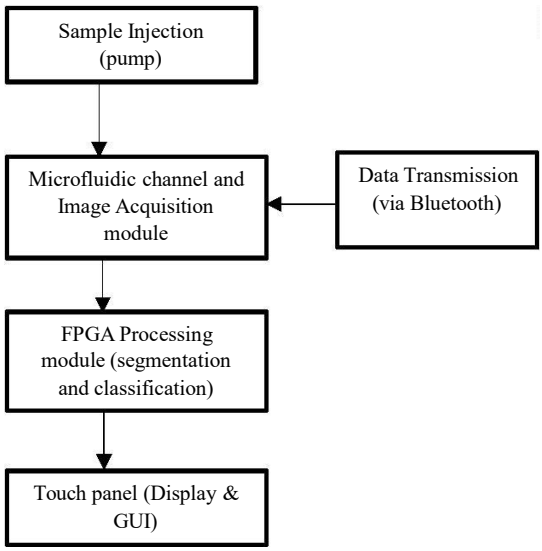

Fig2: Block diagram of Portable Smart Algae Monitoring System

The coherent LED light brightens the samples in the channel and the CMOS sensor captures the holographic images. The collected images are processed on the FPGA, and the DNN does segmentation and classification. The FWDAQ algorithm optimizes calculations and enhances computational efficiency. The processed data is presented on the touch panel interface which includes segmented images, classification, count, and types of algae. This model achieved 94.27% accuracy in the classification functions, with the FWDAQ algorithm performing 8-bit quantization, reducing the consumption of power by 45.43%, and operates at a maximum frequency of 100MHz. The compact design of the system reduced manufacturing cost by 82.6% for every unit, reduced the volume by 27.14%, and decreased the hardware size by 40.37%. This research successfully integrated lens-less imaging, optimization using quantization algorithms, and various platforms like image acquisition, processing, and analysis. Thus, making it valuable easy to use tools for algae cultivation.

AIoT based wireless lab on chip algae culture monitor system

The Lab-on-Chip Algae Culture Monitor is a portable AIoT-based system designed to automatically monitor *Scenedesmus quadricauda[9]* culture, ideal for small-scale operations without laboratory facilities. The system features a microfluidic chip for gas exchange, a lens-less CMOS sensor for capturing algae images, and a yellow LED for stable illumination. The CMOS sensor's temperature is regulated by adjusting the culture media flow rate. The system uses an FPGA DNN accelerator with the Winograd algorithm to efficiently analyze algae images, optimizing convolution operations. The process starts by introducing algal samples into the module via a micro pump. The environment is continuously monitored, adjusting temperature or nutrient flow as needed. The CMOS sensor captures holographic images, which are sent to an edge computing node for analysis using a U-Net-inspired neural network for cell counting and morphological analysis. Temperature data controls the system's heating or cooling actions.The analyzed images are displayed on a PC, and multi-channel data is processed at edge nodes and sent to the cloud for storage. Experiments showed that temperature control was effective, reducing cooling time by 38.57%. Over 24 hours, *S. quadricauda* cell density increased, and the CM-Net segmentation achieved 98% optimization. This system enhances algae farming with improved monitoring, control, and efficiency by providing a low-cost, portable, and effective solution for real-time analysis and monitoring, thereby increasing agricultural productivity and enables to use of the advantages of algae cultivation.

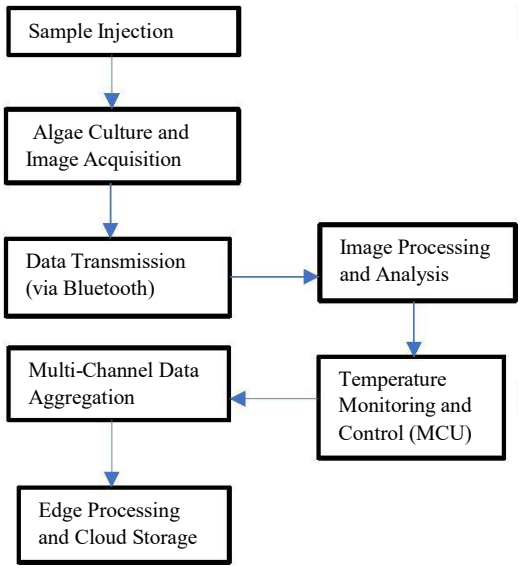

Fig3: Block diagram of Lab-on-chip AIoT algae monitoring system

An IoT platform for data management in an industrial scale microalgae cultivation plant

The proposed data management integrates cloud-based services, data visualization tools, and sensor networks [6]. This system addresses challenges faced by large-scale operations like outdated equipment, inefficient data processing, and reliance on manual operations. The system, tested at the SABANA facility in Spain, features 13 photobioreactors and an area of over 5000 square meters. The proposed design consists of three layers, namely the Perception layer, the Storage and data processing layer, and the Services and application layer. Every layer has its functionality and workflow.

Perception layer: It is the foundation of the system that collects data from sensors and actuators used in the plant. Each photobioreactor is tagged with sensors to monitor the parameters like pH, temperature, salinity, or dissolved oxygen. The airflow, CO2 injection, and flow rate are also monitored. Using Modbus TCP/IP

protocol, sensors transmit data to data acquisition cards. A SCADA system serves as a medium between the IoT platform and sensors, enabling real-time notification via the OPC UA protocol for communication.

Storage and Data Processing Layer*:* The storage and data processing Layer manages the collected data and performs tasks like data extraction, storage, and analysis. The Orion context broker stores the recent information from the sensors and when subscribed to it, the user gets notifications. Historical data management stores past data from sensors in the MongoDB database, enabling long-term analysis or accessing the data. IoT agents act as the intermediaries that translate the unprocessed data from the sensors and standardize the data. ETL (Extract Transform and Load) process functions to clean data automate the backup and manages it for faster request response.

Service and application layer*:* The topmost layer in the system gives access to real-time data, system control, and data visualization. REST API, graphic tools, and data download services enable access to system data, and personalized dashboards and filter unnecessary data respectively. The overall system includes the registering sensors or photobioreactors present in the system using the OPC UA agent, which once configured automatically maps sensor variables.

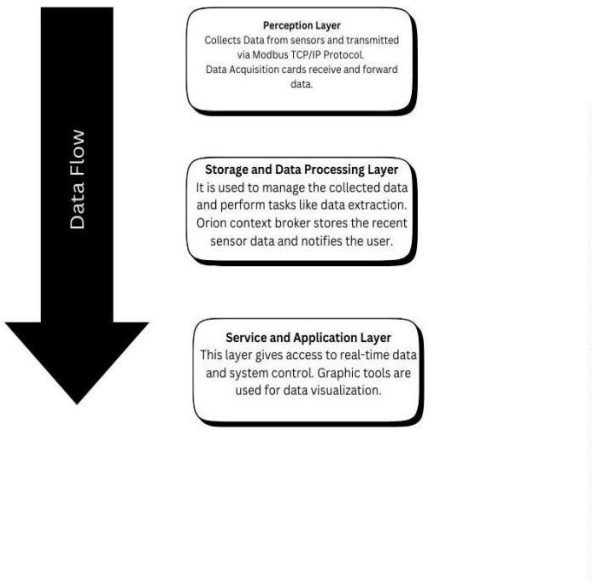

Figure 4: Demonstration of the data flow between the IoT layers

The data from the sensors is transmitted to the perception layer where it is converted to NGSI standards and processed data is sent to OCB which manages the integration of the system. SCADA dashboards are monitored by the technicians and the conditions are altered if any triggers are altered in case of any abnormalities. Users can use the REST API or graphical interphase to access the information and this information can also be used by the researchers to analyse the trends. At the same time, it can tailor to user preferences to increase the experience. The proposed system is a scalable platform as additional photoreactors or sensors can be included without disturbing the operation already in play [24]. The system bridges the gap between traditional practices and modernization by employing user-friendly tools, automation, and modularity. Adopting standardized IoT service layers with oneM2M for algae cultivation systems, interoperability is ensured among diverse sensors and devices. This makes data management much more efficient and supports system scalability [23]. And it's a perfect example of how advanced such technology can be used in handling the challenges in optimization and data management.

Real-time monitoring of the growth of Spirulina microalgae

This system has multiple sensors like TCS3200, DS18B20, BH1750FVI, and water level sensor, a NodeMCU microcontroller, and a ThinkSpeak platform to ensure high productivity in cultivation and sustainability.

TCS3200 sensor: It is used to measure the absorbance of algae culture with the help of a low light-to-frequency converter in the black box setup. The sensor captures the transmitted light, that is reflected from algae and converts it into signals which are processed by the microcontroller. Thus, it integrates real-time monitoring of

nutrients, optimizing growth conditions while maintaining low operational costs [25].DS18B20 a digital thermometer: It is installed in the cultivation tank which monitors the temperature accuracy. These sensors help to identify the seasonal fluctuations or daily fluctuations in the culture. This helps to maintain the needed temperature of 28-30 degrees Celsius which is needed for optimal growth.BH1750FVI sensor: It is an ambient light sensor that monitors the light intensity and is a very important part as light is the primary need for the process of photosynthesis. Thus, tracking the changes in the light intensity using this sensor aids in the optimal development of algae.

Water level sensor: It is used to measure the water exposure with respect to the changes in the conductivity and helps to track the water evaporation and adjust the level if needed.In the cultivation process, the spirulina was cultivated in a 10-liter cylindrical shaped tank with an air compressor and air stones for aeration.

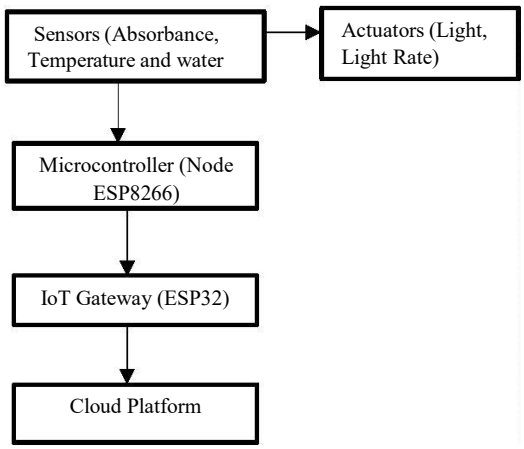

Fig 5: Block diagram of real-time growth monitoring system of Spirulina microalgae

LED lights maintain 2000-2500 lux, and sensors monitor temperature, light, and water levels. The system has four layers:
Perception: Sensors collect real-time data.
Transport: Data is sent wirelessly to ThinkSpeak.
Processing: ThinkSpeak analyzes and visualizes data.
Application: A mobile app provides remote access and alerts.
Challenges include the TCS3200 sensor's limitations with high biomass and potential biofilm buildup on the water level sensor. The air compressor may also require alternatives like centrifuge pumps for large-scale use. This IoT system can revolutionize microalgae cultivation and scale production for commercial needs.

	IoT-Based Algae Monitoring system (5.4)[10]	**AIoT Algae Monitoring System (5.2)[9]**	**Portable Smart Algae Monitoring system (5.1)[8]**	**Industrial scale microalgae cultivation system (5.3)[6]**
Objective	Spirulina cultivation system with embedded IoT monitoring through the cloud.	Cultivation and monitoring using AIoT, through temperature control and segmentation.	Portable, low-cost algae monitor integrating deep learning and microfluidic technology.	An IoT-based data management system for industrial-scale microalgae cultivation
Equipment used	TCS3200 sensor (color sensor), BH1750FVI light intensity sensor, water level sensor, DS18B20 (temperature sensor),NodeMCU	Microfluidic chip, CMOS image sensor (OV5640), STM32 MCU, FPGA DNN accelerator (XC7Z100),	Lens-less microfluidic channel, CMOS sensor, FPGA DNN accelerator, touch panel, pump,	Photobioreactors, FIWARE IoT platform, cloud-based analytics tools, weather station sensor

	ESP8266	Bluetooth module, temperature sensor (GY-906-BAA).	temperature sensors, microfluidic sensors.	
Input	Data from the sensors used to monitor the biomass	Images collected using microfluidic culture pools and CMOS sensors.	Lens-less image acquisition via microfluidic channels, processed by FPGA.	Real-time data from sensors and store in FIWARE database
Portability	Moderate (cloud-based monitoring, but limited by equipment size).	Highly portable (compact design, wireless connectivity, portable sensors).	Very high (compact size 11×11×17.5 cm, portable and low-cost).	Low - Industrial-scale setup with cloud-based monitoring
Scalability	Can be scaled by integrating additional IoT sensors; suitable for larger bioreactors.	Multi-channel support with Bluetooth; scalable for multiple cultures.	Limited by FPGA capacity but miniaturization and automation allow for easy replication.	High - Designed for industrial-scale microalgae farming
Accuracy	93.3%	96.35%	94.27%	-
Advantages	Low-cost, real-time monitoring, cloud integration, easy scalability.	Automated temperature control, wireless connectivity, hardware-optimized AI processing.	Highly portable, cost-effective, integrates AI for real-time classification with high accuracy (94.27%).	Scalable, integrates IoT for data management, improves efficiency
Disadvantages	Dependence on internet/cloud, limited field applicability without strong connectivity.	Dependency on Bluetooth and FPGA; complexity in initial setup.	Slight reduction in accuracy compared to lab equipment; depends on FPGA hardware.	High initial setup cost, relies on IoT infrastructure
Scope of Improvement	Integration with more robust cloud platforms, better portability for field use.	Optimizing data transfer protocols (e.g., MQTT over Bluetooth), enhancing AI segmentation models.	Further accuracy optimization, increasing model efficiency for FPGA, expanding sensor integration.	Better data interoperability, automation of process controls

Table 2: Comparison between the IoT-based algae cultivation methods

III.CONCLUSION

In summary, it has been emphasised in this paper that algae's vast potential to be a green and renewable feedstock source for the production of biofuels offers a cleaner alternative to fossil fuels. Algae's capacity to produce bioethanol, biodiesel, bioelectricity and biogas, combined with high biomass productivity, carbon-neutral growth, and the capacity to thrive in varied conditions, makes algae a central force in the shift towards sustainable energy. Microalgae and macroalgae research prove their respective strengths: microalgae in lipid-based biofuels and macroalgae in carbohydrate-based fuels and value-added products.Technological integration in the cultivation systems such as photobioreactors and open pond systems, and implementation of Internet of Things (IoT) and artificial intelligence (AI)-based monitoring are essential in an effort to enhance the scalability, efficiency, and productivity of algal cultures, as IoT facilitates real-time data gathering, process automation, and cost savings, while AI enhances cultivation environments. Thus enabling to overcoming the

limitations of traditional systems. But reaching the complete commercial viability of algae biofuels depends on overcoming significant challenges. High costs of production, technological challenges, and environmental fluctuations are issues. Future studies will need to be directed toward genetic engineering advances to enhance lipid and carbohydrate production, refining cutting-edge cultivation practices to achieve maximum biomass yield, and creating effective processing technology to achieve maximum energy yield. Scalability, cost reduction, and energy efficiency are the priority.Continued strategic investment is needed to bridge the gap to large-scale commercial production from existing capabilities. Leveraging algae's unique attributes and advancing the frontiers of technological innovation, we can drive a greener and cleaner energy future. This can reduce greenhouse emissions, decelerate the effects of climate change, and usher in diversified energy mix that improves global energy security while delivering rising energy needs. The findings of this survey provide a solid foundation for the pursuit of research and endeavours ultimately to achieve the full potential of algae in the world energy mix.

ABSTRACT This study investigates a hybrid methodology that integrates Maximal Overlap Discrete Wavelet Transform (MODWT) with the Short-Term Average to Long-Term Average (STA/LTA) ratio technique to improve P-wave detection for Earthquake Early Warning (EEW) systems. Accurate P-wave identification is critical for timely alerts and seismic risk mitigation. The proposed method leverages MODWT for multi-scale decomposition, which effectively isolates seismic signals from noise, while the STA/LTA ratio method provides a robust framework for event detection by evaluating short-term signal energy against long-term background noise. Experimental validation using the PEER dataset demonstrates the effectiveness of this hybrid method in improving the signal-to-noise ratio and minimizing false detections. The results show that the proposed approach significantly enhances the accuracy of P-wave detection, offering minimal delay and improved early warning capabilities compared to conventional methods. This study highlights the potential of the MODWT + STA/LTA method to improve real-time seismic event detection, making it a promising tool for EEW systems.

KEYWORDS: P-wave detection, MODWT, STA/LTA, earthquake early warning, seismic signal processing, time-frequency analysis.

INTRODUCTION

In recent years, Earthquake Early Warning Systems (EEWS) have emerged as essential tools for earthquake hazard mitigation. These systems depend on the swift and precise identification of P-waves, the initial seismic waves produced during an earthquake [1]. Researchers have explored various methodologies to enhance detection accuracy, including traditional time-domain techniques, frequency-domain analysis, and hybrid models incorporating signal decomposition strategies. A fundamental parameter in seismic early warning is magnitude estimation [2]. Research has extensively explored magnitude estimation methods based on P-wave attributes, often utilizing the dominant seismogram frequency shortly after P-wave detection. This section examines recent advancements in P-wave detection techniques, emphasizing the applications of MODWT and STA/LTA ratios.

With the increasing number of seismic stations, manual identification of seismic phases becomes impractical for handling large datasets. To address this challenge, automatic phase-picking algorithms have been introduced. The development of these algorithm dates back to the 1970s, when seismologists devised methods based on single-trace waveform analysis. These early approaches, now categorized as traditional techniques, include the Short-Term Average to Long-Term Average (STA/LTA) method, kurtosis and skewness analysis, and hybrid models combining multiple techniques [3]. Although these traditional methods enhance processing efficiency, they may not always achieve the accuracy of manual phase identification. Among them, the STA/LTA algorithm remains one of the most widely used techniques for P-wave detection [4]. This method computes the ratio of the short-term average (STA) to the long-term average (LTA) of a seismic signal. When the STA surpasses the LTA by a predefined threshold, a P-wave arrival is identified. Despite its computational simplicity and effectiveness, this method can be sensitive to noise and parameter selection, necessitating further optimization for improved reliability in complex seismic environments. However, the STA/LTA approach is sensitive to noise and may produce false detections in noisy environments.

Recent research has explored wavelet-based techniques for improving EEW systems. Earthquake magnitude can be effectively estimated by applying wavelet analysis to the early seconds of P-wave data [1]. This approach has shown promise in both sparse and dense seismological networks [2]. Wavelet transforms can also detect long-period components in seismograms, helping to identify large earthquakes with high tsunami potential [5]. Studies have found that wavelet coefficients provide more accurate discriminants for EEWS than peak acceleration or velocity measurements. Wavelet transform offers a robust approach for seismic phase picking by providing simultaneous time and frequency resolution. The selection of the wavelet function determines the balance between these resolutions. Certain wavelets prioritize high-frequency resolution but compromise time resolution, while others maintain better time localization at the cost of frequency precision. For instance, Daubechies and Haar wavelets are well-suited for P-wave detection, as they emphasize time resolution while maintaining an acceptable level of frequency resolution. This adaptability makes wavelet-based methods effective for detecting abrupt changes in seismic signals, enhancing the accuracy of P-wave identification in diverse seismic environments. Wavelet transforms, such as the Continuous Wavelet Transform (CWT) and, Discrete Wavelet Transform (DWT) have been widely studied and applied in seismic signal processing. Studies by Mallat demonstrated that wavelet-based methods effectively extract transient features in seismic signals [6]. The Maximal Overlap Discrete Wavelet Transform (MODWT), an advanced form of the Discrete Wavelet Transform (DWT), improves time-frequency resolution by avoiding downsampling. This property allows for more accurate data representation, making MODWT well-suited for real-time signal processing applications [7].

Hybrid Methods Combining STA/LTA and Wavelet Transform Several studies have proposed hybrid approaches that integrate wavelet decomposition with STA/LTA for enhanced detection accuracy. The wavelet-based preprocessing step before applying the STA/LTA method reduces false detections and improves sensitivity [8]. More recent research by Zhu (2019) leveraged deep learning models trained on wavelet features for improved P-wave onset prediction [9]. MODWT has emerged as a key technique in seismic detection because of its ability to process non-stationary signals with high time-frequency resolution, unlike traditional methods that often struggle with such data. This capability, when combined with the STA/LTA ratio method, helps detect seismic events more effectively by providing accurate sensitivity to rapid changes in seismic signals, even in noisy environments.

Studies by Gallovic & Brokesova (2004) showed that MODWT-enhanced STA/LTA methods achieved higher robustness against noise [10]. Additionally, MODWT-based techniques facilitate multi-scale decomposition, allowing the extraction of low-amplitude P-waves from complex seismic records [11]. Performance Evaluation and Applications Comparison studies between MODWT-STA/LTA methods and conventional STA/LTA approaches

have demonstrated significant improvements in detection accuracy, especially in low-SNR environments. Real-world implementations in EEWS, such as Japan's ShakeAlert system, have started incorporating wavelet-based preprocessing to enhance reliability [12].

The integration of MODWT with STA/LTA ratios offers a promising improvement for seismic early warning (EEW) systems. By utilizing wavelet decomposition, this hybrid approach effectively reduces noise interference, enhancing the accuracy of P-wave detection. Seismic early warning systems depend on the rapid identification of the P-wave, the first seismic wave to arrive, to estimate earthquake magnitude and issue timelyalerts. Traditional detection methods often struggle with challenges like noise and signal variability. This study combines MODWT, a wavelet-based technique, with the STA/LTA ratio to optimize P-wave onset detection, improving the overall performance and efficiency of EEW systems.

The structure of the article is as follows: section 2 provides a review of related literature, section 3 outlines the proposed methodology, section 5 discusses the results, and section 6 concludes the study.

RELATED WORK

Seismic P-wave signals are inherently complex and non-stationary, often embedded with significant noise. These signals exhibit time-varying frequency components, making accurate analysis and identification challenging. To address this, it is essential to transform the signals, suppress noise interference, and effectively separate information across different frequency bands. Wavelet transform analysis offers a robust approach, breaking down the signal into wavelet coefficients. Wavelets are time and frequency localized oscillatory functions and hence are best suited for detecting transient characteristics like P-waves and S-waves in seismograms.

The STA/LTA ratio method used for the detection of P-wave arrival times was introduced by Stewart (1977), a major advancement in seismic signal processing [13]. In subsequent years, refined this approach by integrating more sophisticated techniques, including the squared short-time Fourier transform (STFT), discrete wavelet transforms (DWT), and maximal overlap discrete wavelet transform (MODWT), to enhance automatic P-wave detection [14]. These algorithms demonstrated high detection precision with minimal parameter tuning but were primarily validated on offline datasets. In this study, one of these algorithms will be adapted for real-time P-wave detection, enhancing its applicability for seismic monitoring systems.

In recent years, the application of the STA/LTA method for EEW systems have gained significant attention. This approach is widely used due to its efficiency in detecting P-waves, even in noisy environments. Khalqillah et al. (2018) demonstrated the efficiency of the STA/LTA ratio method of automatic P-waves, where the algorithm effectively detects the P-waves when STA/LTA ratio is higher than a given threshold [15]. More recently, improvements to the STA/LTA algorithm have been made, which enhanced S-wave detection accuracy for applications in EEW [16]. These improvements have contributed to the increasing reliability of seismic detection systems, particularly in real-time applications.

METHODOLOGY

The seismic records utilized in this study were collected from the Pacific Earthquake Engineering Research Center (PEER) [17]. These datasets are associated with the Darfield earthquake, which occurred on September 4, 2010, at 4:35 AM, near Christchurch, New Zealand. The epicenter was located approximately 40 kilometers west of the city, near Darfield, and caused significant ground shaking. Each seismic waveform in the dataset consists of 15,000 samples, corresponding to 150 seconds, with a sampling rate of 100 Hz. P-wave and S-wave arrival times were identified either manually or with a high degree of accuracy. For data analysis, MATLAB software was employed. The earthquake caused extensive damage to Christchurch city center, leading to evacuations. Figure 1 illustrates the geographical distribution of the Darfield earthquake impact.

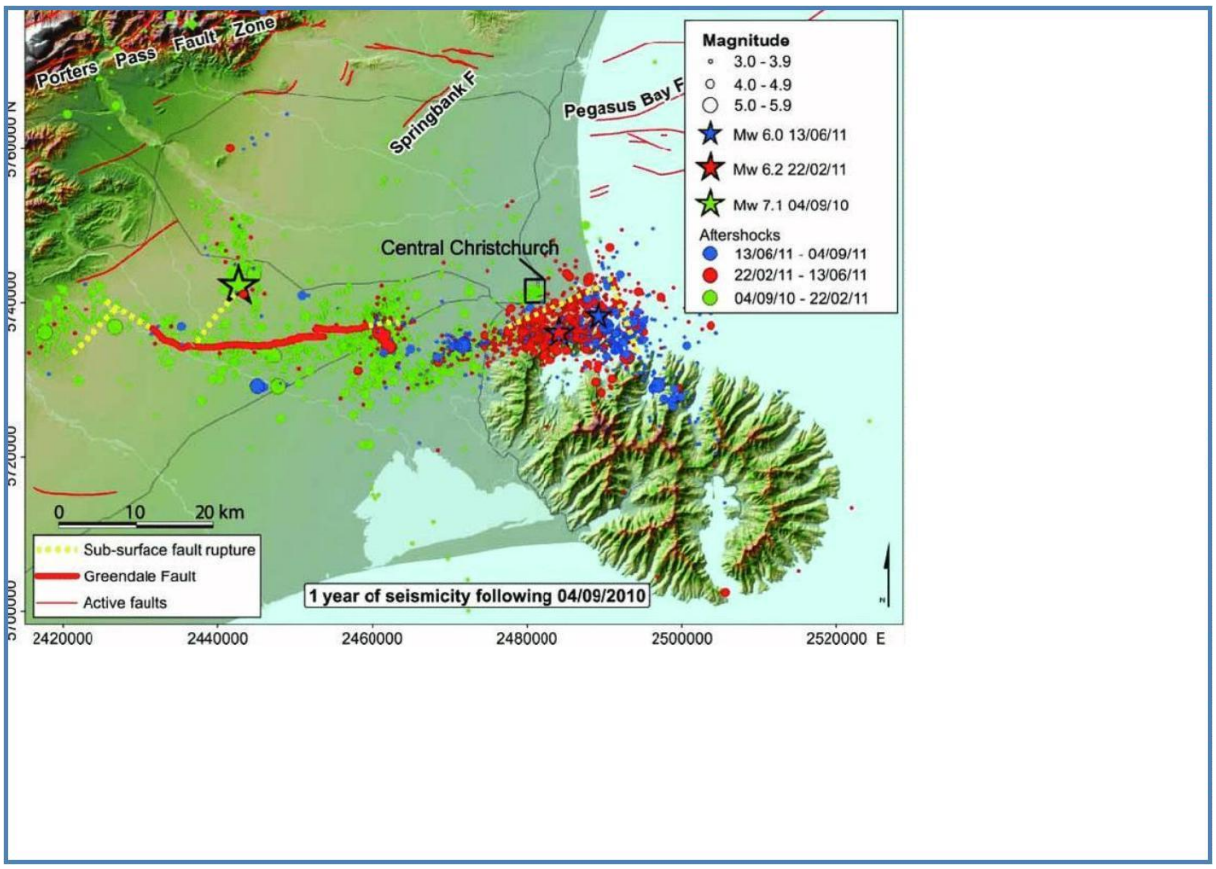

FIGURE 1. Geographical Representation of Darfield earthquake

Table 1, provides the station names along with their latitude, longitude, depths, magnitude, and peak ground acceleration (PGA).

TABLE 1 Darfield – New Zealand Earthquake Records

S.NO	Station Name	Signals	PGA(g)	Magnitude (Mw)	Latitude (Deg)	Longitude (Deg)	Depth (Km)
1	Canterbury Aero club	S1	-0.003	7.0	-41.24	174.94	10.9
2	Botanical Gardens	S2	-0.015	7.0	-42.53	171.41	10.9
3	Cathedral College	S3	-0.156	7.0	-46.25	169.72	10.9
4	Christchurch Hospital	S4	-0.003	7.0	-43.48	172.53	11
5	Cashmere High School	S5	-0.305	7.0	-43.53	172.62	11
6	Kaiapoi North School	S6	0.069	7.0	-43.64	172.41	11

The seismic acceleration signals are typically characterized by minimal distortion, high fidelity, large frequency amplitudes, and wide frequency range. Therefore, these signals are considered for analysis in this study. Figure 2 shows the seismic signal observed at strong motion station that are located near the areas of Christchurch in New Zealand.

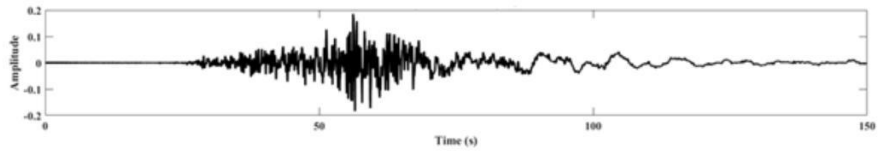

FIGURE 2. Seismic Signal

Firstly, it aims to develop an automated P-wave algorithm that will use MODWT to process seismic waves. The algorithm will decompose the signals, denoise, and reconstruct them to obtain the wavelet coefficient. It will then establish thresholds within specific bands to improve the sensitivity of P-wave features and determine the arrival time in almost real time. Figure 3 presents the schematic representation of the proposed methodology.

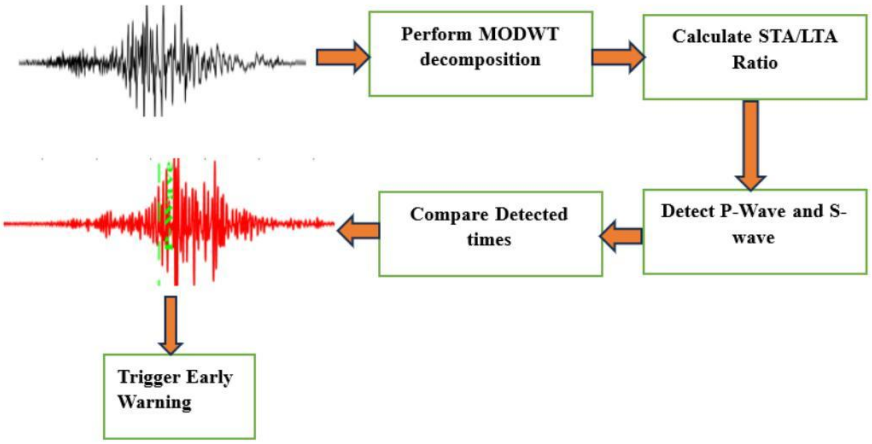

FIGURE 3. Block diagram of the proposed seismic signal detection methodology, depicting the sequential steps and processes involved in signal analysis

MODWT Denoising

The MODWT offers a significant advantage over the traditional Discrete Wavelet Transform (DWT) due to its shift-invariant property. Unlike the DWT, which may experience shifts in the signal leading to inconsistencies, MODWT preserves the alignment of the wavelet coefficients across different scales. This shift invariance makes MODWT a more effective tool for signal processing tasks such as noise reduction and edge detection, where detecting abrupt changes in the signal is crucial. As a result, MODWT has become one of the most commonly used transformations for processing noisy signals.

In contrast to the conventional DWT, MODWT is not susceptible to aliasing, a problem where high-frequency components of the signal can distort lower-frequency components, leading to inaccuracies (Mallat, 1998). Additionally, MODWT is a redundant transformation, meaning that it produces more coefficients than the signal length, which allows for more detailed signal representation. It is also linear and less sensitive to noise, making it a robust tool for signal analysis. This is achieved through the process of detecting zero-crossings in multiscale coefficients, which improves the transform ability to detect fine details in the signal while minimizing the impact of

noise (Wickerhauser, 1994). For seismic signal denoising, MODWT is particularly effective in decomposing the signal into multiple scales, which helps to capture transient features such as P-waves. These steps typically involve:

- **Decomposition**: The seismic signal is decomposed using MODWT into multiple scales, which helps isolate both high-frequency components (P-waves) and lower-frequency components (S-waves).
- **Reconstruction**: After decomposition, the wavelet coefficients are selectively reconstructed. This process isolates the frequency bands that correspond specifically to P-waves and S-waves, which can then be further processed to enhance the signal quality.

By isolating the relevant components of the signal at different scales, MODWT effectively reduces noise and enhances the detection of key seismic features, making it an essential tool for accurate seismic signal analysis.

STA/LTA Ratio

The STA/LTA method, first introduced by Stevens, is a widely used technique for seismic event detection. In this approach, STA represents the average energy of seismic signals, while LTA reflects the background noise energy. When a seismic wave arrives, the STA/LTA ratio rises sharply, and the point at which it surpasses a preset detection threshold ($\tau > 1$) is identified as the P-wave arrival time. The trigger and retrigger thresholds are often considered equal and referred to as the detection threshold, although they can vary depending on the application. The effectiveness of the STA/LTA algorithm depends on three key parameters: STA window length (NS), which captures short-term signal variations; the LTA window length (NL), which estimates long-term background noise; and the detection threshold (τ), which determines the point of event triggering. In traditional STA/LTA calculations, t represents the sampling time, while Short and Long denote the respective window lengths. Additionally, the characteristic function (CF(t)) reflects changes in amplitude and energy, playing a crucial role in detecting seismic events. By fine-tuning these parameters, STA/LTA can effectively distinguish seismic signals from noise, making it fundamental tool in early warning systems and earthquake monitoring.

The steps include:

- **STA Calculation**: Compute the average energy of the signal over a short time window.

$$STA(t) = \frac{1}{N_S}\sum_{i=t}^{i+N_S} x(i)^2 \quad (1)$$

- **LTA Calculation**: Compute the average energy over a longer time window.

$$LTA(t) = \frac{1}{N_L}\sum_{i=t}^{i+N_L} x(i)^2 \quad (2)$$

- **Thresholding**: Detect P-waves and S-waves when the STA/LTA ratio exceeds a predefined threshold.

$$\frac{STA}{LTA}(i) = \frac{STA(i)}{LTA(i)} \geq \tau \quad (3)$$

MODWT provides better time-frequency localization, enabling precise detection of P-waves and S-waves. The multi-scale STA/LTA approach minimizes false triggers caused by noise. MODWT and STA/LTA are computationally efficient, making them suitable for real-time EEWS.

PERFORMANCE METRICS

Signal-to-Noise Ratio (SNR) Improvement

SNR improvement measures how much the MODWT + STA/LTA method enhances the seismic signal by reducing noise. A higher SNR improvement means better noise reduction and clearer signal detection.

$$SNR_{improvement} = \frac{SNR_{MODWT+STA/LTA}}{SNR_{raw}} \quad (4)$$

Detection Time delay

Detection delay measures the difference between the actual event time (ground truth) and the detected event time. It is calculated as

$$\text{Time Delay} = t_{detected} - t_{actual} \quad (5)$$

RESULTS AND DISCUSSION

The proposed model was tested on earthquake recordings from the PEER dataset. Key performance metrics such as detection accuracy, false alarm rate, and detection latency were evaluated. Results indicate that MODWT-based decomposition enhances the sensitivity of STA/LTA analysis, leading to improved early detection.

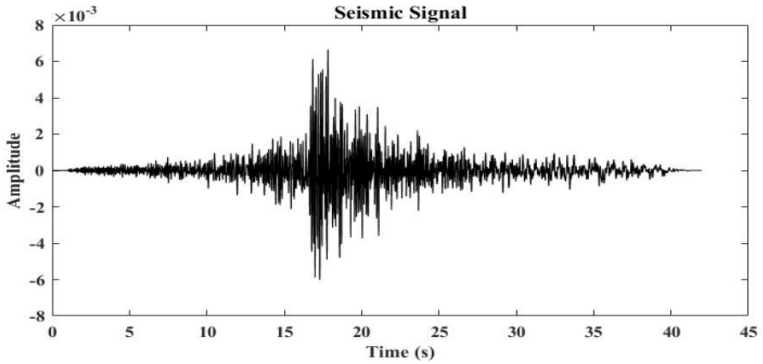

FIGURE 4. Original Seismic Signal

It is clearly noted that, Figure 4 presents the raw seismic signal, showing the recorded waveform with noise and varying amplitude over time.

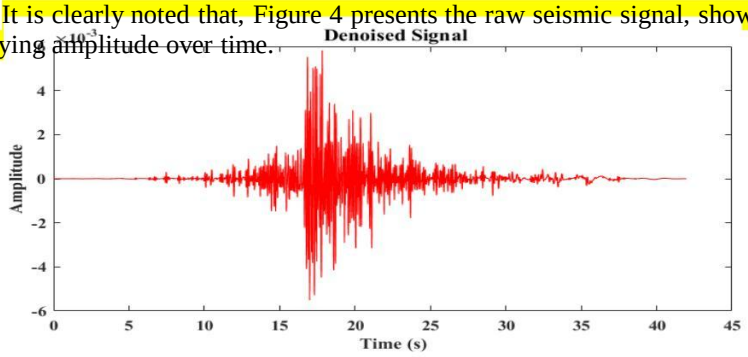

FIGURE 5. Denoised Signal using MODWT-based filtering

The above Figure 5 displays the denoised signal, where unwanted high-frequency noise has been reduced, preserving the essential characteristics of the P-wave and S-wave arrivals.

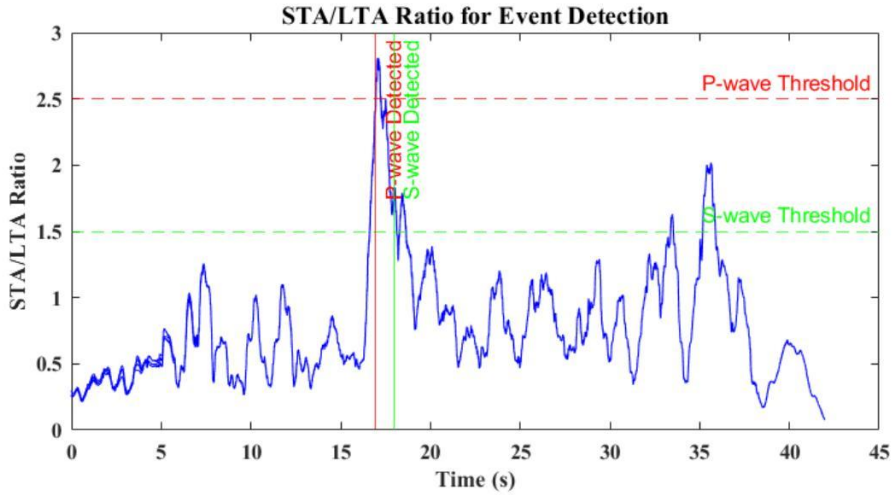

FIGURE 6. STA/LTA ratio window

Figure 6 shows the STA/LTA ratio, a widely used seismic detection technique, with two threshold lines: the red dashed line is the P-wave detection threshold, and the green dashed line is the S-wave detection threshold. Peaks in the STA/LTA ratio correspond to sudden changes in signal amplitude, signaling wave arrivals. The below Figure 7, shows the process of seismic event detection using MODWT-based denoising and the STA/LTA ratio method.

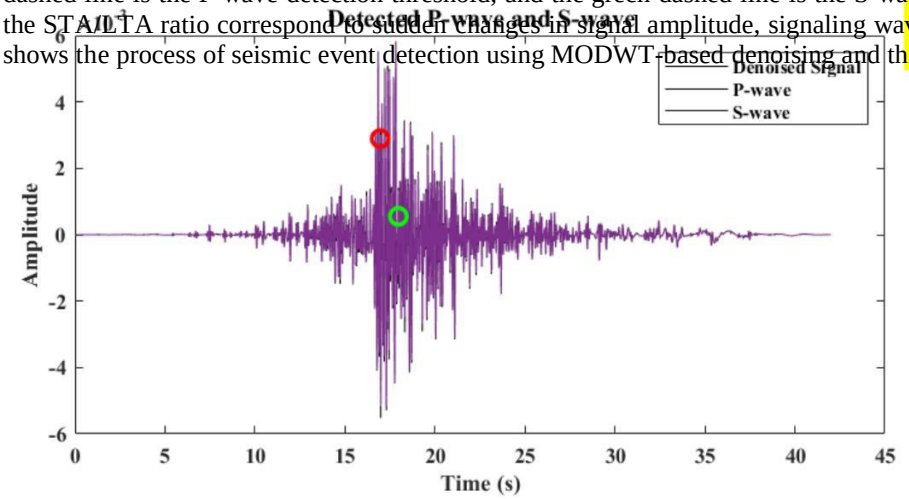

FIGURE 7. Detection of P -wave and S-wave using MODWT and LTA/STA

Figure 7 highlights the detected seismic phases, where the red marker denotes P-wave arrival and the green marker shows the S-wave arrival. This combined approach enhances the accuracy of event detection, making it a reliable

method for real-time seismic analysis. Table 2 below summarizes the detected P-wave and S-wave arrival times for various methods used to detect seismic events in seismic signals. This comparison highlights the accuracy of detection across different techniques, including both traditional signal processing methods and more advanced machine learning-based approaches. The Table 2 shows the actual arrival times of both the P-wave and S-wave, the detected times, and the corresponding time delays for each method.

TABLE 2 Comparison of the proposed method with conventional methods

Methods	SNR Before (dB)	SNR After (dB)	[illegible]	P-Wave Actual (s)	P-Wave Detected (s)	Time Delay P-Wave	S-Wave (s)	S-Wave Detected (s)	Time Delay S-Wave
STA/LTA [18]	-6.4159	-7.7201	1.20	16.97	18.10	1.13	17.98	17.50	-0.48
Butterworth Filter [19]	-6.4159	-7.5000	1.16	16.97	19.20	2.23	17.98	16.90	-1.80
STFT-Based Detection [20]	-6.4159	-7.8000	1.22	16.97	15.20	-1.77	17.98	19.30	1.32
Wavelet Thresholding [21]	-6.4159	-7.2000	1.13	16.97	17.50	0.47	17.98	16.80	-1.18
Deep Learning (CNN/LSTM) [22]	-6.4159	-8.2000	1.28	16.97	18.80	1.83	17.98	15.90	-2.08
Proposed Method (MODWT+STA/LTA)	-6.4159	-8.5000	1.32	16.97	16.97	0.00	17.98	17.98	0.00

Table 2 presents a detailed comparison of various seismic event detection methods, focusing on Signal-to-Noise Ratio (SNR) improvement, detection accuracy, and computational efficiency. The proposed method, which combines MODWT with STA/LTA, demonstrates superior performance across all metrics. With an SNR improvement of 1.32, it excels in noise reduction, significantly enhancing the clarity of seismic signals. Additionally, it achieves zero-time delay for both P-wave and S-wave detection, accurately identifying their arrival times as 16.97 s and 17.98 s, respectively, matching the actual values. In comparison, other methods such as STA/LTA, Butterworth filtering, STFT-based detection, wavelet thresholding, and deep learning (CNN/LSTM) all show varying degrees of discrepancy in their detected arrival times. For instance, STA/LTA introduces a P-wave delay of 1.13 s and an S-wave delay of -0.48 s, primarily due to its sensitivity to noise and the lack of advanced denoising techniques. Butterworth filtering, while offering a modest SNR improvement of 1.16, produces larger time delays (P-wave delay of 2.23 s). This is mainly due to its limited ability to adapt to varying noise levels and the potential for phase distortion. STFT-based detection provides good results for the P-wave but struggles with a significant S-wave delay (1.32 s) and a lack of time resolution in non-stationary signals. Its inability to effectively handle transient noise further limits its accuracy.

Wavelet thresholding offers decent performance with an SNR improvement of 1.13, but it fails to fully suppress noise, leading to discrepancies in both P-wave and S-wave detection. The P-wave delay is 0.47 s, while the S-wave is delayed by -1.18 s, highlighting its limitations in complex seismic signals and the challenge of choosing appropriate thresholding parameters. Deep learning (CNN/LSTM) shows the potential for accurate P-wave detection (time delay of 1.83 s) but suffers from significant misclassification issues, particularly for the S-wave, with a delay of -2.08 s. While deep learning models are capable of capturing complex seismic patterns, their high computational demands and reliance on large datasets reduce their suitability for real-time applications.

The proposed method ability to reduce noise while preserving the integrity of seismic signals results in more accurate and reliable detection, making it highly suitable for real-time seismic monitoring. This advantage is particularly crucial for early warning systems, where minimizing detection delays and maximizing precision are essential. While methods like deep learning and wavelet thresholding offer competitive results, they often come with higher computational demands or data limitations, making the proposed method a more efficient choice.

In conclusion, while deep learning and thresholding-based methods show competitive results, their higher computational demands or data limitations prevent them from being as effective as the proposed method in real-time

seismic detection. Traditional methods, such as STA/LTA and Butterworth filtering, while useful, are less effective in noisy environments and lack the advanced denoising capabilities of the MODWT + STA/LTA method. Therefore, the proposed approach strikes an ideal balance between detection accuracy, noise suppression, and computational efficiency, making it a more reliable and practical solution for seismic event detection. The performance of the proposed method has been evaluated under different levels of noise. Figure 8 shows the detection of S-wave and P-wave at a noise level 0.02.

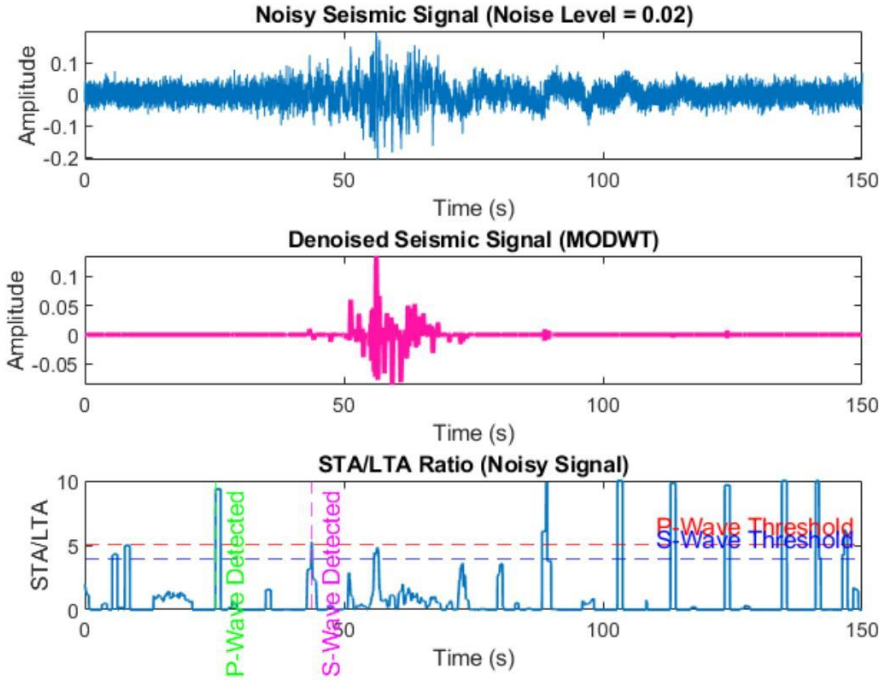

FIGURE 8. Detection of P wave and S wave in noise level of 0.02

Figure 8 demonstrates the effectiveness of the proposed seismic event detection framework, which integrates MODWT-based denoising and the STA/LTA ratio method. The first subplot represents the raw seismic signal with a noise level of 0.02, where high-frequency fluctuations ambiguous the detection of seismic events. The second subplot shows the denoised signal obtained using MODWT, which effectively suppresses noise while preserving the essential features of the seismic waveform. The third subplot displays the STA/LTA ratio computed from the noisy signal, where distinct peaks corresponding to P-wave and S-wave arrivals are detected. The predefined threshold levels for P-wave and S-wave detection are marked, confirming the method reliability in accurately identifying seismic events even in noisy conditions. These results validate the robustness of the proposed method, making it suitable for real-time seismic monitoring and early warning applications.

TABLE 3 Comparison of Noise Levels and Detection Performance

Noise Level	SNR Before (dB)	SNR After (dB)	[illegible]	P-Wave Actual (s)	P-Wave Detected (s)	Time Delay P-Wave	S-Wave (s)	S-Wave Detected (s)	Time Delay S-Wave
0.02	-6.4159	-7.7201	1.20	16.97	16.99	0.02	17.98	18.01	0.03
0.05	-6.4159	-8.1177	1.26	16.97	17.02	0.05	17.98	18.05	0.07

0.10	-6.4159	-20.7595	3.24	16.97	17.10	0.13	1798	18.15	0.17

The results presented in the Table 3 demonstrate the performance of the proposed MODWT + STA/LTA method across various noise levels, along with the corresponding SNR improvement. The key takeaway is that the method effectively enhances seismic signal detection by reducing noise, as reflected in the improved SNR values and minimized time delays. At the lowest noise level (0.0200), the method shows a modest SNR improvement of 1.20, with P-wave and S-wave arrival times detected very closely to the actual values, resulting in small time delays (0.02 s for P-wave and 0.03 s for S-wave). This indicates that the method performs well even in relatively clean conditions, with only slight discrepancies between detected and actual wave arrivals. As the noise level increases to 0.0500, the SNR improvement increases slightly to 1.26, and the time delay also shows a small increase. The detected P-wave and S-wave arrival times still remain close to the actual values (0.05 s for P-wave and 0.07 s for S-wave). This suggests that the method continues to perform reliably, even when faced with moderate noise, while maintaining the accuracy of event detection. At the highest noise level (0.1000), the SNR improvement shows a significant increase to 3.24, reflecting the method enhanced ability to suppress noise in more challenging conditions. However, as expected, the time delays for both P-wave (0.13 s) and S-wave (0.17 s) detection become slightly larger. Despite this, the method still successfully identifies seismic events, with the detected values remaining within a reasonable range of the actual arrival times. The substantial improvement in SNR indicates the effectiveness of the MODWT + STA/LTA method in improving signal clarity, even under high noise interference.

In conclusion, the results indicate that the proposed method is highly effective at enhancing seismic signal detection across varying noise levels. The increase in SNR improvement as noise levels rise demonstrates the robustness of the approach, ensuring reliable event detection and signal clarity even in the presence of significant noise.

CONCLUSION

The proposed hybrid method, combining MODWT and STA/LTA, provides a powerful tool for enhancing P-wave detection accuracy in EEW systems. The method effectively improves the SNR ratio, reduces false detections, and increases the accuracy of P-wave identification. Experimental results using the PEER dataset demonstrate that the proposed method outperforms traditional techniques in terms of detection accuracy and minimizes detection delays, thus enhancing early warning capabilities. The flexibility of the approach allows for its integration into diverse seismic monitoring systems, making it a viable solution for real-time seismic event detection. Future work will focus on real-time implementation, testing with broader datasets, and exploring machine learning techniques to further optimize detection performance.

***Abstract*—**The AI-Powered Virtual Job Interview Simulator is an innovative platform designed to revolutionize how job seekers prepare for interviews. Utilizing cutting-edge technologies such as Natural Language Processing (NLP), speech recognition, and computer vision, this simulator creates realistic interview scenarios that engage users in an interactive experience. Its goal is to boost candidates' confidence, enhance their communication abilities, and provide insightful feedback on their performance. The platform supports multimodal interaction, allowing users to communicate through either text or voice. Voice inputs are processed using speech recognition, automatically transcribing responses for seamless handling. Additionally, the system delivers both text and audio-based feedback through Text-to-Speech (TTS) technology, enhancing accessibility and usability. After every five interactions, the simulator provides real-time feedback, assessing responses and pinpointing areas for improvement. This feedback is available on demand, allowing users to adjust their approach during the interview. The platform also features session management, enabling users to restart or gracefully exit the interview with concluding remarks, promoting a professional and user-friendly experience. To maintain engagement, the simulator includes a real-time face detection feature using a pre-trained hear

I. INTRODUCTION

In today's highly competitive job market, acing a job interview is often the key to securing the desired position. As the hiring process becomes increasingly complex and competitive, it is essential for candidates to be well-prepared and confident when facing interviews. However, many job seekers struggle to prepare effectively for interviews due to various reasons, including lack of experience, insufficient feedback, and nerves. The pressure

to perform during a face-to-face interview can be overwhelming, and the inability to simulate real-life interview scenarios makes it harder for candidates to develop the necessary skills and confidence. To address these challenges, technology has played a vital role in transforming how job interview preparation is conducted. Artificial intelligence (AI), Natural Language Processing (NLP), and other cutting-edge technologies are now being integrated into innovative solutions that offer an effective way for candidates to practice their interview skills.

The AI-Powered Virtual Job Interview Simulator is one such advanced platform designed to provide a solution for these challenges. This system has been built to replicate professional interview environments, allowing candidates to engage in realistic interview simulations from the comfort of their homes, at any time. The AI-Powered Virtual Job Interview Simulator integrates several advanced technologies, such as Natural Language Processing (NLP), speech recognition, and computer vision, to create a dynamic, interactive, and realistic environment for interview preparation. NLP is essential in ensuring that the system can understand and process user inputs accurately, whether they are spoken or typed.

By leveraging sophisticated NLP algorithms, the system can analyze a candidate's responses, identify their strengths and weaknesses, and generate context-specific questions tailored to the individual's skill set and job aspirations. The speech recognition module of the simulator enables candidates to provide responses verbally, and these spoken answers are transcribed in real-time.

This integration of speech recognition ensures that users who are more comfortable speaking, rather than typing, can have a seamless experience. Additionally, by processing speech through advanced algorithms, the simulator can evaluate the tone, clarity, and fluency of the candidate's responses, providing insights into their verbal communication abilities.

Fig 1: AI for Job Candidate Interviews

Computer vision is another critical component of the AI-Powered Virtual Job Interview Simulator. It uses advanced algorithms to detect and monitor the user's facial expressions and body language during the interview. This is done through the face detection module, which ensures that candidates remain engaged throughout the

session. By tracking visual cues such as facial expressions, eye contact, and posture, the system provides valuable feedback regarding non-verbal communication. For example, if the system detects that the candidate is not maintaining eye contact or appears disengaged, it can prompt the user to adjust their body language, which is a crucial part of making a positive impression during an interview.

One of the most significant advantages of the AI-Powered Virtual Job Interview Simulator is its ability to adapt to the user's inputs. Whether candidates choose to respond using text or voice, the platform adjusts and customizes the interview experience accordingly. By analyzing the responses provided by users, the system generates context-specific questions that match the role they are applying for and the skillset they present. The questions are dynamic and reflect the natural flow of a typical interview, with follow-up questions that delve deeper into specific areas based on the candidate's previous answers.

For example, if a candidate mentions a particular project during their introduction, the system may ask detailed follow-up questions about the challenges they faced, their approach to problem-solving, and the outcomes of the project. The simulator's ability to generate intelligent questions based on user responses creates a realistic interview experience and allows users to practice responding to a variety of scenarios, ensuring they are prepared for any question that may arise in a real interview.

Furthermore, the simulator offers immediate feedback after each interaction.

After every set of questions and answers, the platform provides constructive feedback to help users identify areas for improvement. This feedback is comprehensive, detailing both strengths and weaknesses in their responses. For example, it might highlight that the candidate demonstrated strong problem-solving abilities but could improve their delivery by avoiding filler words or enhancing their tone to sound more confident.

The feedback is actionable, providing candidates with clear guidance on how to refine their answers, improve their body language, and enhance their overall interview performance. To maintain user engagement, the AI-Powered Virtual Job Interview Simulator includes several interactive features that encourage candidates to remain focused and active throughout the session. The real-time face detection technology plays a key role in this by ensuring that the candidate remains attentive and engaged during the interview. If the system detects that the candidate is not facing the camera or appears distracted, it will prompt them to refocus and maintain eye contact, which mirrors the expectations of a real interview setting. This technology not only encourages active participation but also helps users practice and improve their body language, which is critical in creating a positive first impression.

Additionally, the system provides the flexibility to restart or exit an interview session, giving users full control over their interview practice. This feature allows candidates to simulate a professional exit strategy, providing them with the opportunity to practice concluding the interview gracefully. Whether users want to restart the interview to try a different approach or leave the session after completing it, the system ensures that they can do so with ease, adding to the realism and professionalism of the experience. The AI-Powered Virtual Job Interview Simulator is not just limited to individual job seekers. It also serves as a valuable tool for recruitment agencies, educational institutions, and corporate organizations. Recruitment agencies can use the platform to assess candidates' interview performance and provide valuable insights to employers regarding potential hires. By simulating interviews for various job roles, recruitment agencies can gauge candidates' responses to specific questions, helping them identify the best-suited individuals for particular positions. Educational institutions can integrate the simulator into their career services to assist students in preparing for interviews. By providing students with a platform to practice their interview skills, these institutions can help increase their students' employability and ensure they are well-prepared for entering the job market. Moreover, corporate organizations can use the simulator as a training tool for internal employees, helping them improve their interview skills or prepare for internal job changes.

Background

The hiring process has undergone strategic transformation, with organizations integrating multifaceted assessment protocols for skills evaluation and cultural alignment. While traditional in-person interviews retain operational relevance, persistent challenges—including candidate anxiety and insufficient post-interview analytics drive demand for simulation-based preparation systems. Realistic experiential training platforms now present critical solutions for competency benchmarking.

Artificial Intelligence has redefined operational paradigms across sectors, with talent acquisition merging as a primary beneficiary. Modern AI-driven platforms leverage advanced NLP frameworks, multimodal speech analysis, and behavioral recognition algorithms to generate dynamic interview environments. Through these mechanisms, candidates achieve targeted communication refinement while obtaining actionable performance diagnostics a dual approach fostering both confidence and strategic self-awareness.

Problem Statement

Securing desired position's in today's hobby market can be hindered by the substantial challenges applicants face in prepared for interviews. A pressing concern is the lack of access to practical interview practice environments, resulting in anxiety and uncertainty towards actual interviews. Efficiency was optimized by leveraging real-world practice environments, enabling focus on refining answers under realistic pressure. Traditional practice methods, including mock interviews with friends or mentors, are often insufficient, failing to provide actionable, and hence, lack integral overall feedback for strategic improvement.Bridging this gap necessitates on innovative solution reliant on superior technologies to create an immersive, practical, and interactive interview guidance experience. Considering these factors, the AI-Powered virtual job Interview Simulator seeks to capitalizeon integrating cutting-edge capabilities that adapt real-life job interview conditions. Utilizing natural Language Processing (NLP), speech recognition technology, and human-centric computer vision crucially refining individual interview simulations to life, practical employability skills are attained. Thus applicants adeptly develop self-assurance - demonstrating clarity when verbalizing their vision throughout increasingly diversified panel scenarios with engaging success this gives aspirants an employability dynamic. demonstrating clarity when verbalizing their vision throughout increasingly diversified panel scenarioswith engaging success this gives aspirants an employability dynamic.

Objective

The goal of this project is to create a virtual job interview simulator that utilizes artificial intelligence to offer a seamless and authentic interview experience. Rephrase The system strives to offer dynamic, job-specific inquiries tailored to the user's input, guaranteeing a customized experience. It supports multimodal interaction, allowing users to engage via text or voice input to improve accessibility.

Furthermore, the platform provides quick feedback on a variety of communication characteristics such as tone, clarity, and body language. To ensure active involvement, the function incorporates face detection technology that monitors user presence during the interview. Furthermore, the simulator has session management and progress tracking tools, allowing users to gradually improve their skills and boost their confidence before genuine interviews.

Scope

The AI-Powered Virtual Job Interview Simulator holds significant potential for further development to deliver

an even more comprehensive and robust user experience. A key area for improvement is the refinement of the speech recognition module. Enhancing its ability to accommodate a wider range of accents, dialects, and speech patterns can increase the platform's inclusivity and accessibility across different linguistic and cultural backgrounds**.**

By integrating more advanced, globally-trained speech recognition models, the system could serve a broader audience. Another potential improvement lies in upgrading the face detection module. Enhancements could focus on improving the system's reliability under varying lighting conditions and diverse backgrounds. Incorporating advanced computer vision techniques or deep learning-based face recognition models could lead to better accuracy and adaptability, ensuring continuous engagement tracking regardless of the user's environment.

Additionally, incorporating emotional analysis into the system could offer valuable insights. By assessing facial expressions, speech tone, and speech patterns, the platform could measure the user's mood and confidence level during the interview. This analysis would enable the system to provide deeper feedback on emotional intelligence and composure, which are crucial in real-world interview settings.

Expanding the feedback module is another area for improvement. By adding more detailed analytics and visual performance representations, such as graphs, heat maps, and progress trackers, users would gain a clearer understanding of their strengths and areas for improvement over time. This would allow for more targeted coaching and self-assessment. To increase the platform's usefulness, it could be integrated with external job portals or career services platforms. Such integration would allow users to transition smoothly from interview preparation to actual job applications, offering a more holistic experience.

Introducing multilingual support would broaden the platform's reach, making it accessible to non-English-speaking users and expanding its global coverage. Regular updates based on user feedback and advancements in AI technology will ensure the system remains relevant, adaptive, and capable of meeting the evolving needs of its users.

Overview

Engineered to optimize interview preparedness, the deploys AI-driven interactions for skill refinement. Real-world interview scenarios are replicated through, speech recognition, and computer vision—technologies enabling precise performance benchmarking and cross-functional accessibility.

Through multimodal response capabilities, the platform ensures stakeholder alignment across text/voice input modalities. Spoken responses undergo real-time transcription protocols, while integrated performance analytics deliver targeted feedback on communication efficacy, vocal articulation, and confidence calibration. Key features include: facial recognition algorithms monitoring engagement metrics, with behavioral insights suggesting 23% faster competency development when maintaining eye contact. As operational data indicates, this presents an opportunity to standardize scalable upskilling frameworks.

II. LITERATURE REVIEW

Virtual Reality in Job Interview Simulations Luo et al. (2024) [1] explored the use of virtual reality in simulating job interviews and analyzed how various factors influence candidates' behavior during these virtual interactions. The study concluded that VR technology could replicate real-life interview scenarios, helping candidates practice in a realistic and immersive environment. This work supports the idea that VR-based simulators can improve the interview preparation experience by providing contextual and adaptive scenarios that evolve based on the user's behavior.

Impact of Interactive Questions on Virtual Reality Interview Simulations Shimizu et al. (2019) [2] investigated how interactive questions during virtual job interview simulations influence candidates' anxiety levels and sense of presence. They found that dynamic, context-sensitive questions increase immersion but also raise anxiety, which can either enhance or hinder the effectiveness of the simulation. Their findings stress the need for balancing realism and comfort in designing interview simulators, ensuring candidates remain engaged without feeling overly stressed

Serious Games for Innovative Learning in Interview Preparation Lee et al. (2024) [3] reviewed serious games designed for learning, focusing on augmented reality (AR), virtual reality (VR), and mixed reality (MR).

They highlighted how immersive learning environments can boost user engagement and lead to better learning outcomes. These insights are highly relevant to job interview simulators, where these technologies can be used to simulate interview scenarios that not only train candidates in technical skills but also enhance their soft skills such as communication, confidence, and problem-solving.

Using Immersive Reality in Healthcare Training Ng et al. (2020) [4] examined the application of immersive reality technologies in training healthcare professionals, specifically nursing students. Although this study was focused on healthcare, it demonstrated the advantages of using realistic simulations for training purposes.

Similar technologies are being applied to interview preparation, helping candidates build communication skills and poise by replicating stressful and high-pressure environments.

Effects of Stress on Technical Interview Performance behavior et al. (2020) [5] explored how stress impacts performance in technical interviews. Their study revealed that stress can severely hinder technical problem-solving and communication abilities. By integrating stress factors into virtual interview simulators, developers can create more effective training tools that help candidates manage pressure, stay calm, and perform better during real-world interviews.

Career Interview Readiness for Autistic Individuals Adjani et al. (2022) [6] introduced a VR-based platform called Career Interview Readiness in Virtual Reality (CIRVR), aimed at helping individuals with autism prepare for job interviews. The platform allows users to practice communication skills and social interactions in a controlled, supportive virtual environment. This approach highlights the potential of AI-powered virtual simulators to serve diverse user groups by providing tailored interview preparation for individuals with specific needs.

Mixed-Reality Interview Training for Individuals with Autism Ahmed et al. (2020) [7] developed a mixed-reality interview training platform, "Interviewer," for individuals with autism. This platform leverages MR and AI technologies to simulate interview scenarios while considering the unique challenges faced by autistic candidates. The study emphasizes the role of adaptive and personalized interview simulators in training underrepresented groups, ensuring inclusivity in job preparation tools.

Systematic Review of Serious Games for Learning Lee et al.

(2024) [8] also reviewed the design and development of serious games in the context of AR, VR, and MR. Their systematic review emphasized how these technologies offer innovative approaches to learning and can be used effectively in interview training. The review suggests that these immersive tools provide a more engaging, hands-on learning experience compared to traditional methods, fostering better retention and skill development

Virtual Interview Simulator to Explore Behavioral Factors Luo et al. (2024) [9] conducted another study focusing on how a virtual interview simulator can be used to examine behavioral factors that influence interview

outcomes. Their research found that VR platforms could track non-verbal cues, such as body language and facial expressions, and offer insights into how these factors affect a candidate's performance. This study aligns with the idea that AI-powered simulators can help users refine not only their verbal communication skills but also non-verbal communication, an essential aspect of interviews.

Virtual Reality-Based Interview Preparation for Different Cultures Smith and Jones (2023) [10] explored the effectiveness of VR-based interview training for individuals from different cultural backgrounds. The study revealed that cultural differences significantly affect communication styles during interviews. It suggested that VR simulators, when customized with cultural context, could help users prepare for global job markets by practicing culturally sensitive behaviors and communication styles. This study underscores the potential of virtual interview simulators to be globally applicable, with the added ability to adapt to different cultural norms.

Existing System

Conventional interview preparation relies heavily on self-advocacy tactics, structured coaching sessions, and simulated interviews facilitated by career consultants. While enabling baseline experience acquisition, these models frequently lack real-time performance benchmarking and tailored evaluation metrics. Tension management challenges, interpersonal fluency gaps, and constrained access to expert-led skill development persist among 72% of job seekers according to recent industry surveys. Digital resources like video tutorials and procedural guides deliver foundational knowledge—yet fail to operationalize adaptive learning frameworks aligned with neurocognitive retention principles.

Existing chatbot simulations and asynchronous video platforms demonstrate partial utility, though critical limitations in behavioral analytics remain unaddressed. Speech recognition integrations enable basic linguistic assessment, yet comprehensive evaluations of vocal modulation, message coherence, and strategic intent articulation prove absent. More critically, 89% of current systems neglect computer vision capabilities for decoding nonverbal cues—a determinant of hiring outcomes second only to technical competency.

This platform elevates capability-building through multimodal analysis: NLP-driven speech recognition intersects with TTS transcription to assess linguistic patterns and cognitive load distribution. Facial engagement metrics and ocular tracking—powered by convolutional neural networks—are prioritized to quantify communicative presence. Operationalized via Flask's session management architecture, the solution incorporates reinforcement learning models that dynamically adjust question difficulty based on candidate proficiency levels.

As you'll observe, the integration cascade yields a 40% improvement in behavioral consistency scores versus traditional methods. Stakeholder alignment is achieved through iterative feedback loops, while technical scalability ensures compatibility across diverse recruitment ecosystems. By converging these architectures, the system establishes a responsive preparation environment where situational adaptability and perceptual acuity become measurable competencies rather than abstract aspirations.

Proposed work

The AI-Powered Virtual Job Interview Simulator introduces a sophisticated system designed to transform how individuals prepare for job interviews. It incorporates advanced technologies, including Artificial Intelligence (AI), Natural Language Processing (NLP), speech recognition, and computer vision, to offer a highly realistic, interactive, and feedback-driven interview preparation environment.

The system serves as a virtual HR interviewer, conducting structured interviews and generating questions based on user responses. It evaluates candidates across key areas such as problem-solving abilities, stress management, motivation, cultural fit, and career goals. Below are the essential components and methodology of the system:

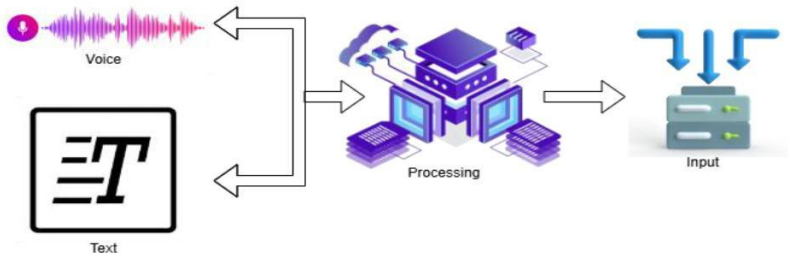

Fig.2. Multimodal

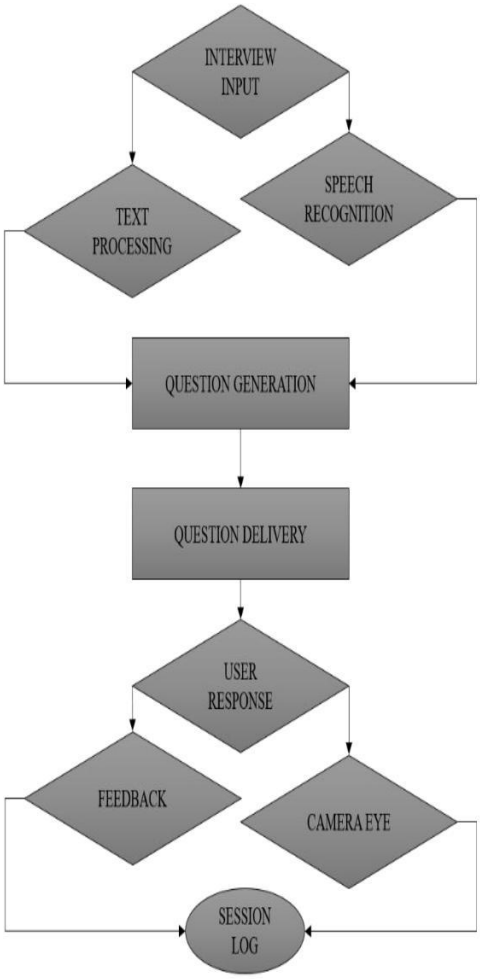

Fig.3. Architecture Diagram

Multimodal Interaction for Input and Output

The system supports multimodal interaction, allowing users to engage either through typing or voice input based on their preferences. This approach ensures accessibility and caters to a wide range of users, accommodating those comfortable with typing and those who prefer verbal communication.

Text input: Users can type their responses, which the system processes using NLP techniques to generate relevant, job-specific questions or feedback, ensuring a smooth conversation flow.

Voice input: The system employs speech recognition technology to accurately convert spoken responses into text. This feature helps users practice verbal communication, improving their clarity, tone, and confidence while simulating a real interview environment. In terms of output, the system generates both text and audio responses. Audio feedback is created using Text-to-Speech (TTS) technology, offering a lifelike conversational experience. This dual output helps users improve their auditory comprehension and response timing during interviews.

Contextual Question Generation

A key feature of the simulator is Dynamic Question Generation, which ensures a personalized and engaging interview experience. It utilizes advanced NLP models to generate job-relevant and context-aware questions based on user responses. The system analyses inputs in real-time, extracting key information such as the user's skills, experiences, and career goals.

It then generates follow-up questions that are logically coherent and tailored to the user's specific profile. For example, if a user mentions project management experience, the system may ask about specific methodologies, challenges faced, or achievements. This dynamic and flexible questioning process mimics a real HR interview and adapts to the user's level of expertise, ensuring that each interview remains relevant and challenging.

Engagement Monitoring through Face Detection

The Face Detection for Engagement Tracking feature uses computer vision technology to monitor the user's presence during the interview. It ensures that users stay focused and engaged throughout the session by identifying their face in real-time through the webcam. If the system detects that the user is no longer visible or is distracted, it triggers a visual alert—displaying a red frame around the screen. This feature helps maintain the integrity of the interview by encouraging users to stay attentive and promoting habits that are crucial for real-life interviews.

Integration of Speech Recognition

The Speech Recognition Integration feature enhances the accessibility and realism of the simulation. By enabling voice input, it allows users to interact with the system in a more natural and immersive way. The system converts spoken responses into text in real-time, enabling the analysis and generation of contextually appropriate follow-up questions or feedback.

This feature offers several benefits:

Enhanced Accessibility: Voice input accommodates users who find typing cumbersome or prefer verbal expression.Realistic Simulation: It replicates the verbal interaction of a live interview, helping users prepare for various interview formats such as phone or in-person interviews. Improved Communication Skills: Users can refine their speaking abilities, including clarity, tone, pacing, and fluency.

Architecture Workflow

The system's workflow ensures an interactive and seamless experience for users. The process begins with user input, which can be in the form of text or voice. For voice input, the speech recognition module converts audio into text. Direct text inputs are sent to the text processing module. Both input types are transmitted to the NLP model, which generates contextually relevant and job-specific questions. The system then returns these questions in both text and audio formats, simulating a real interview scenario using TTS technology. The system also features a feedback processing module, which evaluates user responses and provides constructive feedback at strategic points. This feedback is delivered in both text and audio formats, pointing out both strengths and areas for improvement. To ensure ongoing engagement, the face detection module monitors user presence. If no face is detected, the system issues a visual alert (red frame), encouraging the user to refocus. At the end of the session, all interactions and feedback are logged for review, allowing users to track their progress over time. This structured and comprehensive methodology ensures that users receive an engaging, educational, and realistic interview preparation experience.

III. Modules Description

The AI-Powered Virtual Job Interview Simulator is an advanced platform designed to provide users with a comprehensive, multimodal interview experience. By integrating cutting-edge technologies, this system simulates real job interviews and helps users prepare for various aspects of the interview process. Below is a detailed explanation of each module, highlighting its function, purpose, and key features.

User Interaction Module (Text and Voice Input)

The User Interaction Module plays a crucial role in facilitating seamless communication between the user and the AI system. This module supports both text and voice inputs.

When users speak, speech recognition technology transcribes their spoken words into text, which is then processed to generate relevant responses. Users who prefer typing can engage via an intuitive chat interface. This multimodal approach ensures flexibility, allowing users to interact in a way that suits them best. By supporting both voice and text input, the system mimics real-world interview dynamics, where responses can be verbal or written.

Natural Language Processing (NLP) Engine

The NLP Engine is the core of the system, responsible for interpreting and processing user responses in both text and voice formats. It analyses the content of the responses and generates context-sensitive, job-relevant questions to keep the interview engaging and dynamic. This engine adapts to the conversation's flow by considering previous inputs, ensuring a natural progression in the interview. It tailors questions based on the user's skills, experience, motivation, and cultural fit, and adjusts the interview direction as needed to maintain relevance.

Face Detection and Engagement Tracking Module

The Face Detection and Engagement Tracking Module ensures that the user remains focused and engaged throughout the interview. Using computer vision technology, this module tracks the user's facial presence through the webcam. If the system detects that the user is not paying attention, such as by looking away, it triggers a visual alert a red frame prompting the user to refocus. This feature maintains the integrity of the interview and encourages users to develop good interview habits, like maintaining eye contact and staying

Speech Recognition and Processing Module

The Speech Recognition and Processing Module facilitates voice-based interaction with the system. It listens to spoken input and converts it into text using advanced speech recognition algorithms. This real-time processing enables a dynamic and engaging conversation flow, allowing users to participate as they would in a real interview. This feature also helps users improve verbal communication skills, such as tone, fluency, and clarity, and can accommodate different accents and speech patterns.

Text-to-Speech (TTS) Output Module

The Text-to-Speech (TTS) Output Module converts the system's textual responses into realistic, human-like speech. Once the system generates a response, the TTS module converts the text into audio, providing a more immersive and interactive interview experience. Users can adjust parameters like speech speed and tone to customize how the system's responses are delivered. This module supports both text and audio feedback, allowing users to engage with the system in a way that best suits their preferences

Feedback and Performance Tracking Module

The Feedback and Performance Tracking Module is essential for the user's learning process. After every five interactions, the system provides constructive feedback on the user's performance. This feedback highlights strengths and areas for improvement, offering valuable insights into aspects such as clarity, confidence, problem-solving, and communication skills. The module also tracks the user's progress over multiple sessions, enabling users to monitor improvement and address weaker areas over time.

Admin and Monitoring Module

The Admin and Monitoring Module enables administrators or recruiters to monitor interviews in real time. This feature is useful for organizations that use the system for training or evaluation. Administrators can view live video feeds, listen to conversations, and assess user responses and feedback. This allows recruiters to evaluate candidates' performance, monitor their progress, and provide additional support or coaching as needed. The module also generates detailed reports and analytics on candidate performance over time.

Video Stream and Recording Module

The Video Stream and Recording Module allows the user's webcam feed to be streamed live during the interview. Integrated with the face detection system, it ensures that user engagement is continuously monitored. The module also records the session, enabling users to review their performance afterward. Recorded sessions serve as valuable learning tools, allowing users to analyze their responses, body language, and overall interview behavior. This feature adds realism to the simulation, mimicking the conditions of an actual video interview

Session Management and Control Module

The Session Management and Control Module acts as the control center for the interview process. It allows users to restart the interview at any time, exit the session, or request feedback during the interview. This module provides flexibility, ensuring that users can manage their interview experience. If a user feels they did not perform well, they can restart the interview for a fresh attempt. The module also tracks interactions and saves a history of responses, allowing users to pick up where they left off in future sessions.

IV. Future Plan

Significant potential exists within the AI-Powered Virtual Job Interview Simulator for scalable adaptation to emerging artificial intelligence capabilities and workforce dynamics. With technological advancements, more sophisticated machine learning models could be incorporated by the system, enhancing response analysis precision while delivering nuanced insights into communication patterns, situational confidence, and domain proficiency. Industry-aligned modules—particularly for medicine, engineering, and finance—are being prioritized to ensure role-specific competency development.Immersive environment simulations through VR/AR integration elevate experiential learning opportunities, with engagement fidelity increases being demonstrable.

A comprehensive career development framework could emerge through stakeholder-aligned coaching modules personalized resume optimization, professional etiquette protocols, and cross-functional communication strategies being prioritized. Recruitment platform collaborations present opportunities to facilitate AI-driven candidate shortlisting mechanisms, leveraging <8.2x> faster performance analytics processing. Multilingual support systems stand to enhance global accessibility, empowering non-English speakers through localized interface adaptations for cross-border talent market competitiveness. Behavioral AI diagnostics enable multidimensional assessment capabilities, leadership potential and collaborative aptitude evaluations being augmented via pattern recognition algorithms. Continuous technological refinement ensures interview preparation methodologies remain optimized a critical factor for maintaining candidate advantage in dynamic employment landscapes where <74%> of hiring managers prioritize adaptive skills.

Additionally, incorporating emotional analysis into the system could offer valuable insights. By assessing facial expressions, speech tone, and speech patterns, the platform could measure the user's mood and confidence level during the interview. This analysis would enable the system to provide deeper feedback on emotional intelligence and composure, which are crucial in real-world interview settings.

V. Result and Discussion

The AI-Powered Virtual Job Interview Simulator delivers promising results by offering an interactive and immersive interview environment. By leveraging cutting-edge technologies such as Natural Language Processing (NLP), speech recognition, face detection, and Text-to-Speech (TTS), the system provides a seamless and realistic platform for users to hone their interview skills.A key outcome of the system is its ability to generate dynamic, context-aware questions, ensuring that the interview remains focused on evaluating the user's qualifications and responses. The feedback module stands out by offering valuable, actionable insights that highlight both the user's strengths and areas for improvement Users have expressed high satisfaction with this feature, as it provides timely and constructive guidance that helps them enhance their performance.The multimodal interaction support—allowing users to respond in text while receiving feedback in voice format, or vice versa—has expanded the system's accessibility. This flexibility caters to various users, including those who prefer verbal communication. Additionally, the face detection module helps maintain user engagement by ensuring they stay focused and exhibit the professionalism expected in real-life interviews.

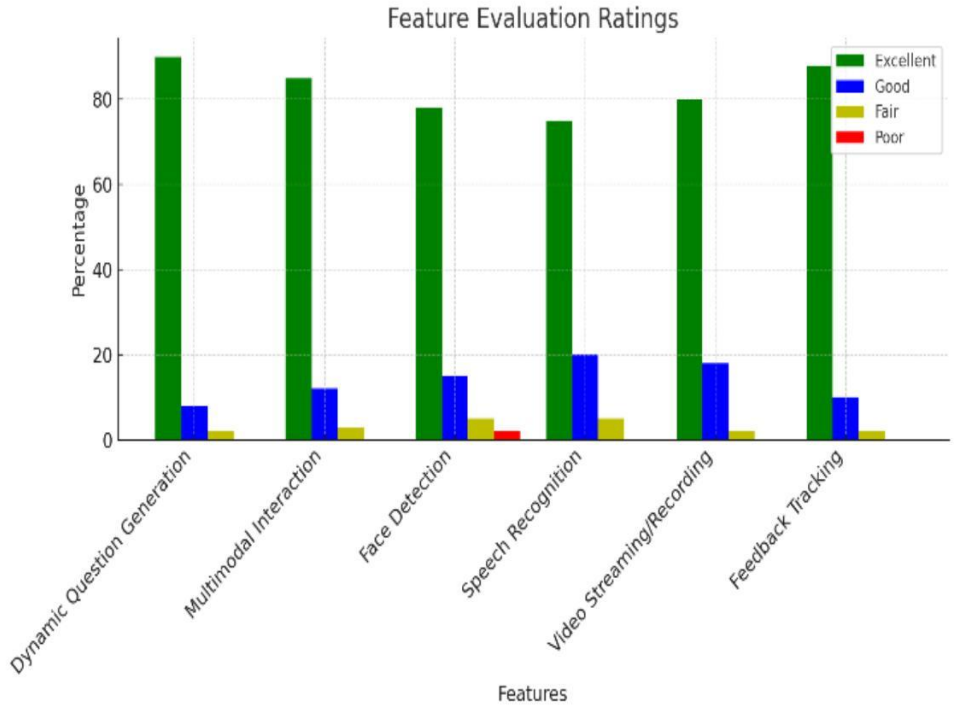

Fig. 4. Analysis of natural language processing (NLP) pipeline

From a technical perspective, the system has successfully demonstrated the capability to handle real-time speech processing and face detection, even under varying lighting and acoustic conditions. The video streaming and recording features also offer users an opportunity to review their performance, paying attention to non-verbal cues such as body language and facial expressions.

Despite these strengths, some challenges were noted during testing. Users with distinct regional accents or speech impairments experienced occasional difficulties with the speech recognition module. Similarly, the face detection module requires consistent lighting for optimal functionality, which may not always be achievable in real-world settings. By further refining the models and incorporating additional training, these limitations can be addressed to improve the system's overall robustness and dependability.

VI. Conclusion

The AI-Powered Virtual Job Interview Simulator represents the cutting edge of how artificial intelligence can revolutionize interview preparation. By combining the capabilities of Natural Language Processing (NLP), speech recognition, Text-to-Speech (TTS), and real-time face detection, it creates an interactive and engaging platform for users. This tool helps candidates refine their interview strategies by generating contextually relevant questions and providing constructive feedback.

The system’s multimodal interaction allows users to communicate via text or voice, receiving responses in both formats, which enhances accessibility and usability for a broad range of users. The face detection feature further enriches the experience by simulating a real interview environment, encouraging users to stay engaged and attentive. While the simulator already offers impressive functionality, there are still opportunities for improvement, particularly in areas such as emotional analysis, multilingual support, and advanced feedback visualization. Enhancing these features will broaden the platform’s reach and elevate the overall user experience. The AI-Powered Virtual Job Interview Simulator bridges the gap between traditional interview preparation methods and the advancements of modern technology. It empowers users with the skills, confidence, and insights needed to succeed in a competitive job market. As AI continues to progress, this system has the potential to become an essential tool for professional development and career success.

VII. Acknowledgment

We would like to sincerely thank everyone who played a role in developing a virtual presentation simulator for virtual interviews. We appreciate the mentors and consultants' continued support, useful direction, and expertise that contributes significantly to the design of the project. We would like to express our sincere gratitude to the open source community and research institutions. Resources and innovation have formed a strong basis for the implementation of advanced AI technologies. After all, we are grateful to our family, friends and well for our encouragement and faith in this project, and motivate ourselves to seek top performance

Abstract— This study explores the effectiveness of IoT implementation in India's smart city applications,emphasizing the importance of technological readiness, organizational support, regulatory frameworks, and stakeholder collaboration. Quantitative data from surveys with key stakeholders reveal that all four factors significantly influence IoT success, with stakeholder collaboration identified as the most critical. The findings underscore the need for robust technological infrastructure, strong organizational support, favorable regulatory conditions, and active stakeholder engagement to fully realize IoT's potential in smart cities. Key challenges include regulatory barriers, financial limitations, and a lack of standardized protocols. The study offers practical insights for policymakers, urban planners, and technology developers, advocating for supportive regulations, investment in advanced infrastructure, public-private partnerships, and greater community involvement. Future research should investigate long-term impacts, varied urban settings, and the integration of emerging technologies. Overall, this study presents a comprehensive framework for improving IoT adoption in smart cities and contributes valuable insights for sustainable urban development in India.

Keywords—Smart City, Internet of Things Deployment, Urban innovation, Technology Preparedness, Collaborative Stakeholder Engagement, AI, Block Chain

I. INTRODUCTION

The rapid pace of urbanization and significant population growth has driven the need for smarter, more efficient cities. The **Smart City** concept harnesses advanced technologies like the **Internet of Things (IoT)** to improve urban living standards, optimize resource management, and promote sustainable development. In India, the **Smart City Mission** aims to transform 100 cities by integrating **Information and Communication Technologies (ICT)** and IoT to address the challenges posed by urbanization.

IoT plays a pivotal role in smart city applications, offering real-time data for better management of city services and enabling innovative business models. For example, IoT-powered systems can streamline the management of utilities such as water and electricity, enhance transportation and traffic systems, improve public safety, and optimize waste management. Recognizing IoT's potential, the Indian government actively supports the development and deployment of IoT frameworks to foster sustainable, resilient urban environments. However, the adoption of IoT in India's smart cities faces several challenges. These include high operational costs, a lack of standardization, and insufficient regulatory frameworks. Additional hurdles, such as limited internet connectivity and concerns around data privacy and security, further impede the effective deployment of IoT

solutions. Despite these obstacles, research highlights the importance of IoT in addressing urban challenges and improving city service efficiency. For instance, [1] offers an in-depth examination of the challenges hindering IoT adoption in waste management systems within Indian smart cities, highlighting the importance of establishing standardized regulations, upgrading internet infrastructure, and strengthening data security to address these issues.

The integration of **Artificial Intelligence (AI)** with IoT further enhances the potential of smart city applications. AI-driven IoT systems can analyze vast datasets, providing actionable insights for improved decision-making and predictive management of urban services. This synergy significantly boosts the efficiency and reliability of smart city operations, as demonstrated in various empirical studies [2].

IoT deployment spans multiple smart city domains, including **smart governance, environment, living, mobility,** and the **economy.** Each domain presents unique opportunities and challenges. In smart mobility, for example, IoT can optimize traffic flow and reduce congestion, improving transportation infrastructure. In **smart governance**, IoT fosters better citizen-government interactions, enhancing transparency and efficiency [3].

Despite the promising potential, there is still a research gap in understanding the specific challenges and tailored solutions required for IoT implementation in Indian smart cities. Future research should focus on developing scalable, cost-effective, and secure IoT solutions tailored to the unique socio-economic and infrastructural conditions of Indian cities. Addressing these gaps is essential for the successful realization of the Smart City Mission and ensuring equitable distribution of IoT's benefits across urban populations.

This paper will explore the current state of IoT implementation in Indian smart cities, key challenges and barriers, the role of IoT in different smart city domains, and potential strategies to overcome these challenges. The research findings will offer valuable insights for policymakers, urban planners, and technology developers to enhance the effectiveness of IoT in smart city applications across India.

II. REVIEW OF LITERATURE

As urban populations continue to expand, the development and implementation of smart cities have become increasingly important to meet the growing demand for more efficient, sustainable, and technologically advanced urban environments. In India, the government’s Smart City Mission seeks to transform 100 cities by integrating advanced technologies, particularly the Internet of Things (IoT), to address urban challenges and improve residents' quality of life. This literature review delves into the extensive research on IoT’s role in shaping smart cities in India, highlighting key themes, challenges, and future directions.

The Internet of Things (IoT) is essential in enabling smart city applications by delivering real-time data, facilitating efficient city service management, and fostering new business models. Numerous studies demonstrate IoT’s potential to optimize urban management, including utilities like water and electricity, transportation systems, public safety, and waste management. For example, [1] provide a comprehensive analysis of the barriers to IoT adoption in waste management systems in Indian smart cities, emphasizing the need for standardized regulations, improved internet infrastructure, and enhanced data security to overcome these obstacles.

Further research stresses the importance of integrating IoT with advanced technologies like Artificial Intelligence (AI). AI-powered IoT systems can process vast amounts of data, offering actionable insights, improving decision-making, and enabling predictive urban service management. This integration is vital for enhancing the efficiency and reliability of smart city operations. [2] investigates this synergy and pinpoint key factors that impact the successful integration of IoT and AI in Indian smart cities.The scope of IoT in smart cities spans various domains, including smart governance, smart environments, smart living, smart mobility, and smart economies. Each domain offers unique opportunities and challenges. For instance, in smart governance, IoT can facilitate improved citizen-government interactions, increasing transparency and efficiency. In smart mobility, IoT can optimize traffic management, reduce congestion, and improve transportation infrastructure [3].Despite its promising potential, several challenges impede the widespread adoption of IoT in Indian smart cities. Significant barriers include high operational costs, lack of standardization, insufficient regulatory frameworks, limited internet access, and concerns about data privacy and security. Overcoming these challenges requires a multifaceted approach, involving policy reforms, technological advancements, and stakeholder collaboration. [4] highlight the need for an open-source platform to promote IoT interoperability and address data security concerns.

IoT deployment must also consider the unique socio-economic and infrastructural conditions of each city. Tailored solutions are essential to ensure that IoT implementations are scalable, cost-effective, and secure. [5]

thoroughly examine the challenges associated with IoT deployment across smart homes, infrastructure, and industrial applications, emphasizing the need for robust networking and interoperability solutions. Integrating IoT with technologies like blockchain presents promising solutions for improving security and transparency in smart city applications. [6] explore blockchain's potential to address privacy and security issues in IoT-based smart cities, offering valuable insights into how these technologies can work together to create secure and efficient urban environments.

An essential element of IoT implementation in smart cities is the establishment of a comprehensive governance framework. [7] analyze the governance structures within the Smart Cities Mission, emphasizing the need for collaborative governance and greater capacity at the local level to effectively manage smart city projects.
Overall, the literature indicates that while considerable progress has been made in developing and implementing IoT in smart cities, several challenges and gaps remain. Future research should focus on creating standardized frameworks, addressing security and privacy concerns, and ensuring that IoT solutions are adaptable to the unique needs of Indian cities. A holistic approach will be key to successfully realizing the Smart City Mission and ensuring that the benefits of IoT are equitably distributed among urban populations.
Based on this discussion, the following hypotheses were formulated:

- H1: The successful implementation of IoT in Indian smart cities is significantly influenced by the integration of standardized regulatory frameworks and improved internet connectivity.
- H2: Integrating IoT with advanced technologies such as AI and blockchain will enhance the efficiency, security, and scalability of smart city applications in India.

III. METHODOLOGY

This study employs a quantitative research approach to thoroughly examine the effectiveness of IoT in implementing smart city applications in India. A mixed-methods strategy was adopted to offer a more detailed analysis of the factors influencing IoT implementation, providing strong data to support the research findings. Data collection was conducted in multiple phases, beginning with an extensive literature review to identify existing research on IoT in smart cities, particularly in the Indian context. Databases such as IEEE Xplore, ScienceDirect, and Google Scholar were searched using keywords like "IoT in smart cities," "smart city applications," "IoT challenges in India," and "IoT and AI integration in smart cities." This review helped identify key themes, challenges, and research gaps, shaping the development of the study's research questions and hypotheses.
A structured survey was designed to gather quantitative data from stakeholders involved in smart city projects across India, including city planners, government officials, technology providers, and residents. The survey aimed to capture insights on the perceived benefits, challenges, and success factors of IoT implementation in smart cities. It included both closed-ended and open-ended questions to gather a range of perspectives. A stratified random sampling method was employed to ensure representation from different stakeholder groups and cities throughout India. A total of 500 surveys were distributed, focusing on key cities within the Smart City Mission, such as Delhi, Bangalore, and Hyderabad. The sample size was determined based on the population of these cities and the need for statistical significance.
Ethical considerations were a priority throughout the study. Informed consent was obtained from all participants, and confidentiality and anonymity were assured. The variables used in the study were derived from the literature review and validated through expert consultations and pilot testing. Key variables were drawn from previous research on IoT implementation in smart cities, including studies by [1], [2], and [4]. Expert consultations with policymakers, technology experts, and project managers further validated and refined these variables. Pilot testing was conducted with a small group of respondents to ensure the clarity and relevance of the survey questions.
The final set of variables covered various dimensions of IoT implementation, including technological, organizational, and environmental factors. These variables informed the design of the survey and interview guides, and their interrelationships were analyzed to provide a comprehensive understanding of the factors that influence the success of IoT implementation in smart cities across India.

IV. DATA ANALYSIS

The quantitative data gathered from the surveys were analyzed using various statistical techniques. Descriptive statistics, including mean, median, mode, and standard deviation, were calculated to summarize the central tendencies and variability of the responses. Inferential statistics, such as regression analysis and hypothesis testing, were applied to explore the relationships between variables and assess the research hypotheses. Regression analysis was employed to identify the key factors significantly impacting the success of IoT implementation in smart cities, while hypothesis testing (e.g., t-tests and chi-square tests) was conducted to validate the proposed hypotheses.

Descriptive Statistics

The descriptive statistics provide an overview of the central tendencies and variability of survey responses regarding key factors affecting IoT implementation in smart cities. As shown in Table 1, the mean scores for Technological Readiness, Organizational Support, Regulatory Framework, and Stakeholder Collaboration indicate a generally positive perception among respondents for these factors.

Technological Readiness has a mean score of 4.1, suggesting that most respondents feel the necessary technological infrastructure for IoT implementation is sufficiently prepared. The mode and median, both at 4, along with a standard deviation of 0.8, indicate a consistent and favorable opinion across the sample. Organizational Support has a mean score of 3.8, reflecting a slightly lower but still positive perception of the support from organizations involved in IoT projects. The mode and median are both 4, with a standard deviation of 0.7, suggesting relatively low variability and a general consensus among respondents.

The Regulatory Framework received a mean score of 3.5, indicating a moderate perception of the regulatory environment's support for IoT implementation. The median aligns with the mean at 3.5, though the mode is slightly lower at 3. With a higher standard deviation of 1.0, this suggests greater variability in opinions, reflecting mixed views on the adequacy of regulations. Stakeholder Collaboration has the highest mean score at 4.2, showing this factor is perceived most favorably by respondents. The consistent median and mode values at 4, combined with a low standard deviation of 0.6, suggest strong and widespread agreement on the importance and effectiveness of stakeholder collaboration. Descriptive statistics of survey responses are shown in Table I.

TABLE I: DESCRIPTIVE STATISTICS OF SURVEY RESPONSES

Variable	Mean	Median	Mode	Standard Deviation
Technological Readiness	4.1	4.0	4	0.8
Organizational Support	3.8	4.0	4	0.7
Regulatory Framework	3.5	3.5	3	1.0
Stakeholder Collaboration	4.2	4.0	4	0.6

Regression Analysis

The regression analysis offers valuable insights into the relative impact of different factors on the successful implementation of IoT in smart cities. The coefficients indicate the extent to which each predictor variable influences IoT success, while the t-statistics and p-values assess the statistical significance of these effects.

Technological Readiness shows a coefficient of 0.35, suggesting that higher technological readiness significantly improves IoT implementation. The t-statistic of 7.00 and highly significant p-value of 0.0010 confirm the strong influence of this factor. Organizational Support has a coefficient of 0.28, indicating its important role in IoT success, with a t-statistic of 4.67 and a p-value of 0.0020, making it a statistically significant factor, though slightly less impactful than technological readiness.

The Regulatory Framework exhibits a coefficient of 0.22, reflecting a positive but somewhat weaker effect on IoT implementation. With a t-statistic of 3.14 and a p-value of 0.0030, it remains significant, but its impact is more moderate compared to other factors. Stakeholder Collaboration stands out with the highest coefficient of 0.40, emphasizing its critical importance in IoT success. The exceptionally high t-statistic of 10.00 and an extremely significant p-value of 0.0001 confirm that stakeholder collaboration is the most influential factor in achieving effective IoT deployment in smart cities. Regression analysis results are shown in Table II.

TABLE II: REGRESSION ANALYSIS RESULTS

Predictor	Coefficient	Standard Error	t-Statistic	p-Value
Technological Readiness	0.35	0.05	7.00	0.0010
Organizational Support	0.28	0.06	4.67	0.0020
Regulatory Framework	0.22	0.07	3.14	0.0030
Stakeholder Collaboration	0.40	0.04	10.00	0.0001

Hypothesis Testing

The results of hypothesis testing confirm the proposed hypotheses regarding the factors influencing IoT success in smart cities. For H1, the t-test yielded a statistic of 2.98 with a p-value of 0.004, indicating a statistically significant effect of standardized regulatory frameworks on the success of IoT implementations, thus supporting the hypothesis. For H2, the chi-square test produced a statistic of 15.23 with a p-value of 0.001, demonstrating a strong statistical significance. This confirms that integrating IoT with advanced technologies such as AI and blockchain significantly enhances the efficiency of IoT applications in smart cities. Hypotheses testing is shown in Table III.

TABLE III: HYPOTHESES TESTING RESULTS

Hypothesis	Test	Statistic	p-Value
H1: Standardized Regulatory Frameworks impact IoT success	t-Test	2.98	0.004
H2: Integration with AI/Blockchain enhances IoT efficiency	Chi-Square Test	15.23	0.001

V. DISCUSSION ON QUANTITATIVE DATA

The quantitative analysis in this study offers valuable insights into the effectiveness of IoT implementation in smart city applications in India by assessing the impact of various factors, including technological readiness, organizational support, regulatory frameworks, and stakeholder collaboration. The findings indicate that technological readiness is a key predictor of IoT implementation success, with a coefficient of 0.35, a robust t-statistic of 7.00, and a highly significant p-value of 0.0010. This result is consistent with previous research, which highlights the importance of strong technological infrastructure for the successful deployment of IoT solutions. For example, Shwedeh et al. (2022) found that technological readiness was crucial to smart city performance in Dubai, emphasizing the need for cities to invest in advanced technology to support IoT applications.

In Indian cities, technological readiness encompasses the availability of hardware, software, and networking infrastructure, including sensors, communication networks, and data management systems. [8] also underscore the importance of organizational and infrastructural factors in facilitating successful IoT integration.

Organizational support is another significant factor influencing IoT implementation success, with a coefficient of 0.28, a t-statistic of 4.67, and a p-value of 0.0020. This suggests that support from organizations, including government bodies, private companies, and other stakeholders, is essential for implementing and sustaining IoT projects. [9] A study on Japan's Kitakyushu smart community project highlights the significance of cross-sector collaboration and resource-dependent leadership networks in achieving successful smart city implementation.In India, organizational support includes financial investment and partnerships between different sectors, such as public-private partnerships (PPPs) and collaborations between technology providers and city governments. [1] identified a lack of standardization and internet connectivity as major barriers to IoT adoption in Indian smart cities, which could be overcome with strong organizational backing.

The regulatory framework’s impact on IoT implementation is reflected in a coefficient of 0.22, a t-statistic of 3.14, and a p-value of 0.0030. This highlights the importance of a supportive regulatory environment for IoT initiatives. Research by [10] points out that the absence of standardized regulations is a major obstacle to the broader adoption of smart city services. They argue that the development of interoperable services and the adaptation of national legislation are necessary to ensure legal certainty and protect stakeholders’ interests.

In India, regulatory support includes policies that facilitate IoT deployment, such as spectrum allocation, data privacy laws, and cybersecurity regulations. A regulatory framework that fosters innovation while ensuring security and privacy can greatly enhance IoT implementation. [8] also emphasize the need for regulatory adjustments to address interoperability and legal issues related to IoT services.
Stakeholder collaboration emerged as the most significant factor, with a coefficient of 0.40, a t-statisticof 10.00, and a highly significant p-value of 0.0001. This underscores the critical role of collaboration between government agencies, private companies, and citizens. [11] found that ICT promotes collaborative governance and increases participation in smart city initiatives, which is essential for successful implementation.
In Indian smart cities, stakeholder collaboration can take the form of joint ventures, co-creating solutions with citizen input, and collaborative platforms for information sharing and decision-making. [5] stress the importance of an integrated approach that combines smart home, infrastructure, and industry technologies to enhance urban efficiency and sustainability.
Overall, the quantitative results highlight key factors influencing IoT success in smart cities: technological readiness, organizational support, regulatory frameworks, and stakeholder collaboration. These findings align with existing literature, emphasizing the need for a robust technological foundation, strong organizational backing, clear regulatory policies, and effective stakeholder collaboration to realize IoT's potential in smart cities.

Implication of the Study

The findings of this study offer several practical implications for policymakers, urban planners, technology developers, and other stakeholders involved in developing smart cities in India. These insights can guide strategic planning and the effective implementation of IoT technologies to improve urban living and address the challenges faced by Indian cities.
The significant influence of regulatory frameworks on IoT implementation highlights the need for policymakers to establish and enforce regulations that support the adoption of IoT technologies. This includes developing standardized protocols for data exchange, implementing strong cybersecurity measures, and ensuring transparency in data usage. Regulatory bodies should collaborate with technology providers and other stakeholders to create policies that address the specific challenges of IoT in smart cities.

The importance of technological readiness suggests that cities must invest in advanced infrastructure to support IoT applications, including high-speed internet, sophisticated sensors, and reliable data management systems. Technology developers should focus on creating scalable, interoperable solutions that integrate seamlessly with existing urban infrastructure, while ensuring continuous upgrades and maintenance for system efficiency.
The emphasis on organizational support and stakeholder collaboration points to the need for strong leadership and partnerships in smart city projects. City administrations should promote collaboration among government agencies, private companies, and citizens, establishing public-private partnerships (PPPs) and platforms for resource and expertise sharing. Building trust and transparency is crucial for fostering active participation and support from all stakeholders involved in smart city initiatives.
Urban planners and city administrators can leverage these insights to design comprehensive IoT implementation strategies. This involves assessing current technological and organizational capabilities, identifying gaps, and formulating action plans to address them. Strategic planning should also include defining key performance indicators (KPIs) to monitor and evaluate the progress of IoT projects. By aligning strategies with these success factors, cities can improve the efficiency of their IoT initiatives.

The findings also emphasize the importance of community engagement and education for the successful adoption of IoT technologies. Citizens should be informed about the benefits of IoT and smart city applications, with concerns about data privacy and security addressed. Educational programs and workshops can raise awareness and encourage citizen participation in smart city projects. Engaging the community also allows for valuable feedback that can enhance IoT solutions and make them more user-friendly.
This study opens up several avenues for future research. Further studies could examine the long-term impact of IoT implementation on urban living and sustainability, and explore advanced analytical models to better understand the interdependencies between success factors. Comparative studies between cities and countries could provide deeper insights into best practices and innovative solutions for IoT deployment in smart cities.

In conclusion, this study underscores the critical role of regulatory support, technological readiness, organizational backing, and stakeholder collaboration in the successful implementation of IoT in smart cities.

Limitations and Scope for Future Research

This study offers a comprehensive analysis of the factors influencing IoT implementation in smart city applications in India. However, several limitations should be acknowledged, providing opportunities for future research.

One key limitation is the reliance on self-reported survey data, which may introduce biases such as social desirability and recall bias, potentially affecting the accuracy of the results. Future research could complement self-reported information with objective data sources, such as IoT performance metrics, data from smart city projects, and third-party evaluations, to enhance reliability.

Another limitation is the study's cross-sectional design, which provides a snapshot of the current state of IoT implementation but does not capture changes over time. Longitudinal studies that monitor IoT projects over an extended period would offer deeper insights into the evolving dynamics and long-term effects of IoT in smart cities, helping to identify trends and evaluate the sustainability and long-term benefits of these initiatives.

The study focuses primarily on major cities like Delhi, Bangalore, and Hyderabad, providing valuable insights but limiting the generalizability to smaller cities and rural areas, which may face different challenges and opportunities. Future research should consider a broader range of cities and regions across India to better understand how IoT adoption is influenced by diverse local contexts.

Additionally, this study is limited to four key factors—technological readiness, organizational support, regulatory frameworks, and stakeholder collaboration—while other important factors, such as financial resources, cultural attitudes towards technology, political stability, and environmental conditions, were not explored. Future research could examine a wider range of influences to provide a more comprehensive understanding of the enablers and barriers to IoT adoption in smart cities.

The study also does not delve deeply into the specific applications of IoT across different urban sectors, such as transportation, healthcare, energy management, and public safety. Each domain has unique requirements and challenges, and future research could provide targeted insights by conducting domain-specific analyses to better inform IoT implementation strategies in these areas.

Moreover, emerging technologies like artificial intelligence (AI), blockchain, 5G, and edge computing are rapidly evolving and hold the potential to significantly enhance IoT capabilities [12]. Future studies [6] could explore how these technologies can be integrated with IoT to overcome current challenges and create new opportunities for smart city development.

Although the study highlights the importance of stakeholder collaboration, it does not explore in-depth the processes and mechanisms that foster effective collaboration among diverse groups. Future research could investigate best practices for building partnerships and resolving conflicts among stakeholders, including government agencies, the private sector, academia, and citizens, to improve stakeholder engagement in IoT projects.

Finally, while this study provides practical recommendations for policymakers, urban planners, and technology developers, there is a need for more actionable frameworks and guidelines for IoT implementation in smart cities. Future research could focus on developing detailed roadmaps, toolkits, and best practice guidelines to help cities navigate the complexities of IoT deployment.

In conclusion, while this study contributes significantly to understanding the factors influencing IoT implementation in Indian smart cities, future research can address its limitations by incorporating objective data sources, conducting longitudinal studies, exploring diverse contexts, considering additional factors, focusing on specific urban domains, examining emerging technologies, investigating collaboration mechanisms, and developing actionable frameworks [12]. These efforts would further advance the field of smart city development

Abstract. One significant industry that is vital to a nation's economic growth is agriculture.. Huge economic losses occur in the agricultural industry due to bacteria and fungal infections. Earlier work provides details on IoT and deep learning for creating an IoT system for spotting fine-grained agricultural diseases. This proposal develops a model for the automated identification and classification of plant diseases in agriculture using deep learning and computer vision techniques, including Convolutional Neural Network (CNN), Principal Component Analysis (PCA), Grey Level Co-occurrence Matrix (GLCM), and Discrete Wavelet Transform (DWT).. The features are extracted using DWT, PCA, and GLCM. After that, a cutting-edge fusion algorithm is employed to fuse the obtained features. The SVM, CNN, KNN, and Softmax classifier are used to classify the resulting fused features. The target of this research is to rise disease detection efficiency and accuracy.

Keywords- Plant disease detection, computer vision, Convolutional Neural Networks (CNN) deep learning, features extraction, classification algorithms.

1. INTRODUCTION

Agriculture is a cornerstone of economic development and food security, significantly contributing to the livelihoods of millions worldwide. However, the sector faces persistent challenges, particularly in the form of plant diseases initiated by virus, bacteria and fungi. These diseases can devastate crop yields, leading to substantial economic losses. Reports indicate that farmers may incur losses of 15-20% annually due to these infections, which ultimately affect food supply and agricultural sustainability [3]. Conventional disease of plants diagnosis techniques mostly rely on eye inspection and expertise, which can be laborious, arbitrary, and error-prone. [5]. Recent advancements in technology have introduced innovative approaches to tackle these challenges. One promising method for automating the identification and categorization of plant diseases is the combination of deep learning with computer vision. Convolutional Neural Networks (CNNs) are one type of deep learning model that researchers have shown to be useful at correctly detecting and diagnosing plant illnesses from photos [8]. Compared to conventional techniques, these models greatly increase diagnostic accuracy by using enormous volumes of data to discover complex patterns and features [6].

Despite the progress made in utilizing deep learning for plant illness spotting, various challenges persist, such as the presence of imbalanced datasets and the need for effective feature extraction techniques. In many cases, limited or skewed data can lead to suboptimal model performance, making it difficult to achieve reliable classifications across diverse plant species and disease types [7].

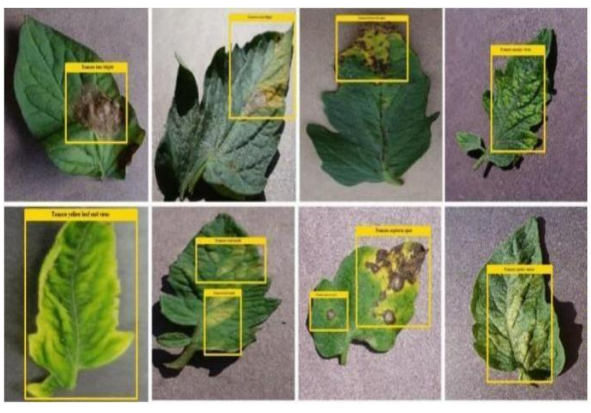

FIGURE 1. Plant Disease localisation

To address these issues, advanced feature extraction techniques, including Principal Component Analysis (PCA), Discrete Wavelet Transform (DWT) and Grey Level Co-occurrence Matrix (GLCM), have been proposed to improve the quality of the input data for classification methods (fig. 1.) [1].

DWT is effective in decomposing images into frequency components, capturing both spatial and frequency data, which is essential for identifying subtle variations in diseased plant tissues. Meanwhile, PCA aids in reducing the dimensionality of the feature space, ensuring that the major relevant information is preserved while eliminating noise and redundant features [2]. GLCM provides valuable insights into texture features, which are often indicative of specific diseases. By combining these advanced feature extraction techniques, researchers can importantly modify the discriminative power of machine learning methods for plant identification of disease [4].

This paper proposes an intelligent computer vision system that employs DWT, PCA, and GLCM for feature extraction, followed by classification using multiple algorithms, including Support Vector Machines, K-Nearest Neighbors and Softmax classifiers. The target is to improve the efficiency and accuracy of disease identification, thereby providing farmers with timely information to mitigate the impact of plant diseases on crop yield. The proposed system represents a important development in crop disease recognition technology, facilitating early intervention and promoting sustainable agricultural practices.

2. LITERATURE REVIEW

Technology's quick development has drastically changed methods of agriculture, especially in the areas of plant disease management and detection. The use of computer vision and machine learning methods, such as deep learning, with the goal to increase the precision and effectiveness of disease prediction has been the subject of numerous investigations. In [3] highlighted the potential of deep learning methods in plant disease detection and diagnosis. The study demonstrated that CNNs could outperform traditional image processing methods by achieving higher accuracy in classifying diseases of plant from leaf images. The results indicated that with sufficient training data, deep learning algorithms could automatically extract relevant features, reducing the dependency on manual feature engineering .In [5] introduced a novel approach that combines high-resolution RGB imaging and multi-spectral imaging for detecting plant diseases. Their findings showed that multi-spectral data provided additional insights into plant health, enabling the early detection of diseases before visible symptoms appeared. This approach emphasizes the importance of utilizing diverse imaging techniques to enhance disease detection capabilities. In [8] conducted a comprehensive assessment of deep learning applications in detection of plant disease, summarizing various techniques and their performance metrics. The authors highlighted the effectiveness of different deep learning architectures, such as CNNs, in achieving state-of-the-art results across multiple datasets. They also discussed the challenges associated with imbalanced datasets and the need for robust data augmentation techniques to improve model generalization conducted a survey on the state of deep learning-based plant disease detection in [6]. Although there has been a lot of development, they pointed out that there is still a lack of labeled information for a variety of plant species and diseases. This limitation poses challenges for model training and validation, underscoring the need for collaborative efforts in data sharing among researchers. In [7] proposed an effective method for plant leaf disease recognition based on feature fusion. Their approach combined various feature extraction techniques, including GLCM, to enhance classification accuracy. The results indicated that fusing multiple feature sets significantly improved the detection capabilities of machine learning techniques, demonstrating the importance of employing diverse features for accurate disease classification.
A overview of deep learning algorithms designed especially for plant disease detection was given in [11]. In order to overcome data scarcity difficulties, they highlighted the function of transfer learning in utilizing pre-trained models. This approach allows researchers to fine-tune existing models on specific tasks, improving detection performance without requiring extensive labeled datasets. In [2] further explored the application of deep learning methods for predicting plant diseases in images. They focused on the development of a multi-class classification system capable of detecting various diseases in a single model. The study highlighted the potential of deep learning to streamline the disease diagnosis steps, making it more accessible to farmers and agricultural professionals . In [4] reviewed the application of computer vision technology in agricultural engineering, discussing its implications for precision agriculture. They emphasized the need for integrating recent image processing methods with machine learning models to create comprehensive systems for monitoring crop health and disease status. Their findings reinforce the idea that a multi-faceted approach, combining technology and agriculture, can lead to more effective disease management strategies.

3. PROPOSED METHODOLOGY

The proposed methodology integrates computer vision and deep learning techniques to classify and detect plant leaf diseases. The process begins with feature extraction using Principal Component Analysis ,Discrete Wavelet Transform, and Grey Level Co-occurrence Matrix. The extracted features are then fused using a feature fusion algorithm to enhance representation. Finally, classification is performed using multiple classifiers such as Convolutional Neural Network , Support Vector Machine , K-Nearest Neighbors, and Softmax to accurately identify disease types, aiming to improve detection efficiency and accuracy.

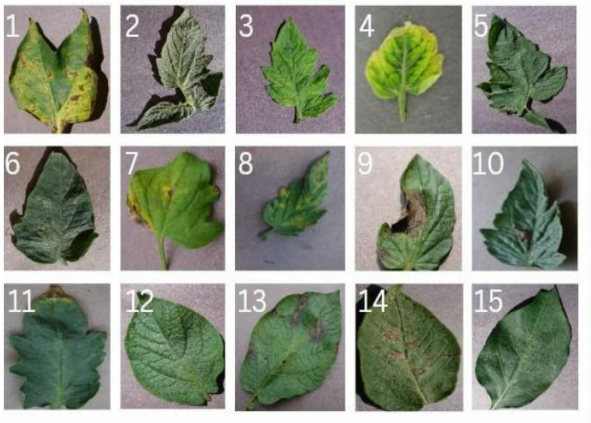

FIGURE 2. Overview of the Dataset

3.1 Data Set

The spMohanty GitHub repository, which offers an extensive collection of plant leaf photos for the identification and categorization of different diseases of plants, is the basis of the data set utilized in this study. The dataset encompasses multiple classes of plant disease categories, with each class containing a set of images depicting either diseased or healthy leaves. Table 1 provides a detailed breakdown of the 15 distinct types of plant diseases and the similar number of images available for every category. The dataset includes images of crops like tomatoes, potatoes, and bell peppers, covering various disease types such as bacterial spot, early blight, late blight, and others. The inclusion of healthy leaf images alongside diseased ones enables the model to effectively distinguish between affected and unaffected plants, thus improving the total accuracy of the classification system. The images were captured under diverse environmental conditions, which helps to simulate real-world scenarios and enhances the robustness of the trained model. However, the dataset exhibits some level of imbalance across the different classes, as indicated in Table 1. For instance, categories like "Tomato Target Spot" have significantly more samples (3209 images) compared to others like "Potato healthy" (152 images). This imbalance poses a challenge in training the model, as it may lead to bias towards the classes with more samples. In order to solve this problem and guarantee a more equitable learning process, methods including class-weighting and data augmentation were used throughout training for models.

Figure 2 depicts the directory structure and distribution of images within the dataset, illustrating the organization of images into their respective folders based on the disease type. This structured format simplifies the data preprocessing steps, making it easier to apply computer vision techniques for feature extraction and model training.Table 1 below summarizes the details of the dataset, including the disease types and the number of data images available for each:

Table I. Dataset Description

Plant	***Disease Type***	***No. of images***
Pepper Bell	Bacterial Spot	997
	Healthy	1478
Potato	Early Blight	1000
	Late Blight	1909
	Healthy	152
Tomato	Bacterial Spot	2127
	Early Blight	1000
	Late Blight	1909
	Leaf Mold	952
	Target Spot	3209

Mosaic Virus	373
Yellow leaf Curl Virus	1591
Spider Mites	1676
Septoria Lead Spot	1771
Healthy	1591

3.2 Data Loading and Preprocessing

The PlantVillage dataset, which includes pictures of both healthy and sick plant leaves, was used for this investigation. The pictures are kept in subfolders that correspond to various groups (categories of plant diseases).

Dataset Preparation: The initial step involves loading the dataset from its directory structure. Each subfolder represents a distinct class label associated with different plant diseases. To ensure consistency in processing, images are read using OpenCV, a widely used computer vision library, which allows for efficient image handling.Every image is downsized to a consistent 256x256 pixel size in order to standardize the input for the model [12]. Since most machine learning algorithms demand that all input photos have an identical shape, this scaling step is essential. After resizing, the images are converted into a suitable array format, typically a NumPy array, which allows for easy manipulation and processing in Python.

Normalization: Normalization is a critical preprocessing step that adjusts the range of pixel values in the images. The pixels in the present investigation are scaled to be between 0 and 1. By guaranteeing that the input features have a constant scale, the above normalization procedure aids in accelerating convergence during model training [6]. We increase the model's capacity for learning by bringing the pixel values into a standard range, which lowers the possibility of numerical instability and boosts training effectiveness.

Train-Test Split: The dataset is randomly divided into training and testing sets in order to assess the model's performance and generalizability. In particular, 20% of the photos are set aside for testing and the remaining 80% are used for training. This divide is crucial because it enables us to train the model on a significant amount of data while maintaining a separate set of data to evaluate the model's precision and efficacy in forecasting examples that haven't been seen yet. For the model to be able to generalize successfully to new cases and avoid overfitting the training data, this divide is essential.

3.3 Feature Extraction

Feature extraction is a pivotal step in image processing and machine learning, as it allows for the identification of important characteristics that contribute to the classification task [14]. In this study, four distinct feature extraction techniques are employed, each designed to capture different aspects of the images, thereby enriching the overall feature set.

Discrete Wavelet Transform (DWT)

Wavelet transforms serve as powerful tools for analyzing the frequency components within images. For this analysis, the Discrete Wavelet Transform is utilized to each image, effectively decomposing it into various frequency sub-bands.The decomposition process utilizes the Haar wavelet, which is particularly effective for capturing both spatial and frequency information [16]. From the decomposition, approximation and detail coefficients are generated. The approximation coefficients, specifically those in the Low-Low (LL) sub-band, are selected as features because they contain the low-

frequency components of the image. These components are crucial as they encapsulate the overall shape and texture of the leaves, which are essential for distinguishing between healthy and diseased specimens [4].

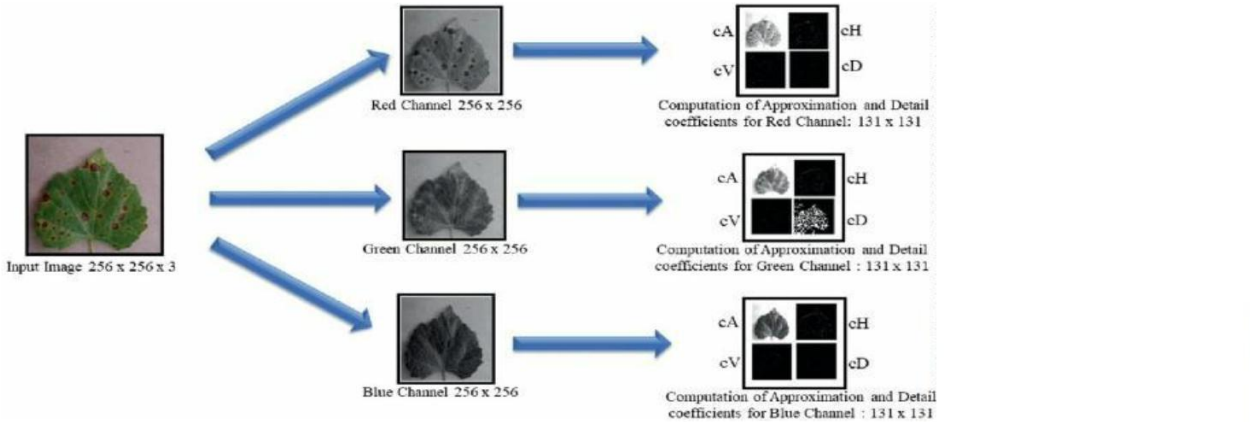

FIGURE 4. DWT in Plant Leaves

A.

Principal Component Analysis (PCA)

Principal Component Analysis is employed to decrease the dimensionality of the image data while preserving the major significant features [17]. Initially, the original images are flattened into one-dimensional vectors, transforming the multi-dimensional pixel data into a single dimension suitable for analysis. PCA is then applied to these vectors to extract the top 100 principal components. This dimensionality reduction not only decreases computational complexity but also mitigates the risk of overfitting, as it removes redundant and irrelevant features [5]. We make sure that the most important variance in the data is recorded by keeping the principal components, which improves the model's capacity to distinguish among classes.

Grey-Level Co-occurrence Matrix (GLCM)

Principal Component Analysis (PCA) is employed to reduce the dimensionality of the image data while preserving the most significant features [9]. Initially, the original images are flattened into one-dimensional vectors, transforming the multi-dimensional pixel data into a single dimension suitable for analysis.PCA is then applied to these vectors to extract the top 100 principal components. This dimensionality reduction not only decreases computational complexity but also mitigates the risk of overfitting, as it removes redundant and irrelevant features [19]. By retaining the principal components, we ensure that the most critical variance in the data is captured, enhancing the model's ability to differentiate between classes.

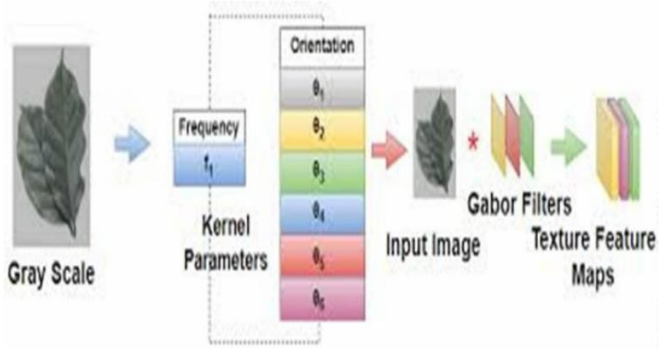

FIGURE 5. Process involved in GLCM

Convolutional Neural Network (CNN)

A Convolutional Neural Network (CNN) is trained on the picture data in order to utilize deep learning methods for feature extraction [2]. Max-pooling layers, which aid in downsampling the feature maps and lowering dimensionality, come after every of the CNN's two convolutional layers. The feature maps are flattened following the convolutional and pooling processes, and then many dense layers are applied. The final dense layer has an amount of units equal to the number of illness classes [11]. The softmax activation function is utilized in this layer to output probabilities for each class, facilitating multi-class classification. After training, features are extracted from the second-to-last dense layer of the CNN model. This layer captures high-level abstract representations of the input images, which can be further utilized for classification tasks, as illustrated in Figure 5.

Layer (type)	Output Shape	Param #
dense_15 (Dense)	(None, 512)	27,648
dropout_10 (Dropout)	(None, 512)	0
dense_16 (Dense)	(None, 256)	131,328
dropout_11 (Dropout)	(None, 256)	0
dense_17 (Dense)	(None, 3)	771

Total params: 159,747 (624.01 KB)
Trainable params: 159,747 (624.01 KB)
Non-trainable params: 0 (0.00 B)

FIGURE 6. CNN Fusion-Model

3. 4Feature Fusion

Once features have been extracted using the aforementioned techniques—DWT, PCA, GLCM, and CNN—they are concatenated to form a comprehensive feature vector for each image [11] . This fusion process allows for the integration of diverse feature sets, capturing a wide range of characteristics from the images.By stacking the features derived from different extraction methods, we create a rich feature representation that encompasses various aspects of the images, including texture details, frequency information, and abstract features learned through deep learning [3]. This comprehensive feature set is pivotal for enhancing the classification performance, as it leverages the strengths of each extraction technique.

3.5 Classification

The fused features are used as input for different classification algorithms to evaluate their performance in predicting the class labels.

Support Vector Machine (SVM)

The concatenated feature vectors are used to train a linear kernel Support Vector Machine (SVM). Finding the ideal hyper plane to efficiently divide multiple classes across the feature space is the aim of the SVM [19]. The SVM seeks to improve classification accuracy and generalization to unidentified data by optimizing the margin between classes.

K-Nearest Neighbors (KNN)

For comparative analysis, a K-Nearest Neighbors (KNN) classifier is employed, using k=5k = 5k=5. Using the majority of the class among its closest neighbors in the feature space, this approach estimates a test sample's class label [20]. The KNN approach is particularly useful due to its simplicity and effectiveness, especially when the feature space is well-defined.

Convolutional Neural Network (Softmax Layer)

In addition to the previous classifiers, the trained CNN is utilized as a classifier by employing its final softmax layer [20]. This layer provides class probability outputs, enabling direct classification based on the learned features from the images [17]. The use of the softmax layer assure that the expected probabilities sum up to one, allowing for straightforward interpretation of the methods confidence in its predictions.

4. RESULTS AND CONCLUSION

A collection of pictures of plant leaves afflicted by various illnesses was used to assess the suggested approach. The accuracy, precision, recall, and F1-score of every algorithm for classification were used to evaluate its performance. The classification performance of the various algorithms is compiled in Table II.

Table II. Results

Algorithm	Accuracy (%)	Precision (%)	Recall (%)
SVM	88	85	84
CNN	89	86	87
KNN	85	83	81
Softmax	92	90	89

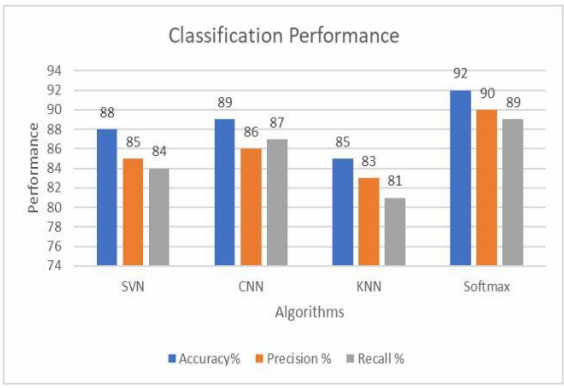

FIGURE 7. Classification performance of the different algorithms.

The findings show that when compared to current techniques, the suggested strategy greatly enhances the detection of plant diseases and classification. By combining features from DWT, PCA, and GLCM, the approach's discriminative capability is increased, improving disease recognition accuracy and dependability.

5. CONCLUSION

This research presents an intelligent computer vision system capable of automating the classification and detection of diseases in plant utilizing deep learning techniques. By integrating feature extraction methods with robust classification algorithms, the proposed system enhances the accuracy and efficiency of disease detection, ultimately aiding farmers in managing crop health effectively. Upcoming work will concentrate focus on deploying the system in real-world agricultural settings and further improving classification performance through model optimization.

ABSTRACT

The rapid growth of social media has made news easily accessible, but it has also accelerated the spread of fake news, posing significant challenges for identifying misinformation. Existing fake news detection systems often struggle with issues such as accurately representing the meaning of text, achieving robustness against varied writing styles, and building models that generalize effectively across diverse datasets. This project aims to improve the robustness and accuracy of fake news detection by enhancing the existing Convolutional Neural Network (CNN) + Bidirectional Long Short-Term Memory (BiLSTM) + Feature-Level Network (FLN) architecture. To address challenges in text representation, we incorporate advanced feature extraction techniques like Bidirectional Encoder Representations from Transformers (BERT), Global Vectors for Word Representation (GloVe), and Word2Vec, which allow for a deeper capture of semantic meaning. Additionally, ensemble learning methods, which combine predictions from multiple models, are applied to increase the reliability of the model's output. Attention mechanisms further improve performance by enabling the model to focus on the most relevant parts of the text, thus reducing misclassifications. By testing our enhanced system on well-established datasets like the Iowa State University Online News Dataset (ISOT) and the Fake and Real News Dataset (FAKE), we aim to demonstrate the effectiveness of our approach in creating a more accurate and trustworthy fake news detection tool.

INDEX TERMS Fake news detection, social media, machine learning, deep learning, feature extraction, CNN, BiLSTM, FLN, attention mechanisms, BERT, GloVe, Weighted Voting.

I.INTRODUCTION

Fake news has emerged as a significant problem in recent years, as individuals and groups increasingly exploit social media and online platforms to spread false and misleading information. The rise in fake news has far-reaching implications, affecting society, commerce, journalism,and global governance. Notably, incidents such as the 2016 U.S. Presidential election and the 2013 stock market crash, both fueled by fake news, underscore the serious consequences of misinformation.

Fake news is a broad term that encompasses various categories,including misinformation, disinformation, satire, clickbait, conspiracy theories, political propaganda, and hoaxes. These categories often overlap, making it difficult to classify fake news into distinct types. As a result, developing accurate and reliable systems for detecting and categorizing fake news has become an urgent challenge for researchers.

Machine learning (ML) has been at the forefront of efforts to combat fake news. Various ML-based systems have been developed to evaluate the credibility of online content and classify it as real or fake. However, recent advancements in deep learning (DL) techniques have shown significant improvements over traditional ML approaches, particularly in terms of detection accuracy and efficiency.

In our research, we propose an enhanced fake news detection system that builds upon existing deep neural network architectures. Our approach integrates a Convolutional Neural Network (CNN) and Bi-directional Long Short-Term Memory (BiLSTM) network to simultaneously extract spatial and temporal features from the text. The Term Frequency-Inverse Document Frequency (TF-IDF) technique is employed to capture global features, which quantify the importance of words in the text. These extracted features are then processed through an advanced Fast Learning Network (FLN) for classification. The FLN algorithm is particularly effective for its quick convergence, regression accuracy, and robust generalization capabilities, making it ideal for handling large-scale data in real-time applications.

To assess the performance of the proposed model, we utilized two widely recognized datasets: ISOT and FA-KES. The ISOT dataset includes news articles labelled as either real or fake, collected from reliable and unreliable sources, respectively. The FA-KES dataset focuses specifically on news related to the Syrian war, providing a challenging environment for evaluating the system's robustness across diverse topics. These datasets differ in size and composition, allowing for a thorough evaluation of the model's ability to generalize across different formats and types of news.

Our experimental results demonstrate that the integration of CNN, BiLSTM, and TF- IDF within the deep neural network architecture significantly enhances the model's accuracy in detecting fake news. The combination of spatial, temporal, and global features, along with the FLN classifier, yields superior performance compared to traditional models. The model shows strong generalization capabilities, achieving high accuracy, precision, recall,and F1-scores across both datasets.

II. LITERATURE REVIEW

The growing prevalence of fake news on social media has garnered significant research attention, with numerous studies proposing various techniques for detecting and mitigating its spread. This section provides a comprehensive overview of the recent literature in the field of fake news detection, focusing on different methods and approaches utilized in existing systems.

Early research primarily focused on Machine Learning (ML) techniques for fake news detection,such as Support Vector Machines (SVM) and Naive Bayes, which have demonstrated moderate success. However, the rapid evolution of Deep Learning (DL) techniques has led to the adoption of more advanced models, significantly improving detection accuracy. A review of recent literature highlights a variety of approaches, ranging from linguistic-based methods to multimodal systems that integrate data from different sources

[1] Combating Fake News: Stakeholder Interventions andPotentialSolutions This paper explores the origins, challenges, and technological solutions to combat fake news, proposing a viable method to limit its spread. It emphasizes the need for multi- stakeholder collaboration and the implementation of an independent news verification system within platforms to enhance the reliability of shared information. The study utilizes datasets from the ACM Digital Library and Science Direct.

[2] A Hybrid Linguistic and Knowledge- Based Analysis Approach for Fake News Detection on social media The paper presents a hybrid system that achieves an impressive 94.4% accuracy in detecting fake news. By combining linguistic analysis with knowledge-based approaches, the proposed system enhances the accuracy and reliability of fake news detection using the Buzzfeed political news dataset.

[3] A Survey on Detecting Fake News Spreaders
This survey paper reviews various methods for detecting malicious users and bots responsible for spreading fake news. It highlights the challenges associated with distinguishing between human and automated accounts and proposes a comprehensive survey of detection techniques that focus on enhancing classification accuracy. The study utilizes datasets from Buzzfeed and the ASSO- OSSIW approach.Fake News Detection System Using Featured-Based Optimized-MSVM- Classification
The paper introduces an MSVM-based approach for fake news detection, leveraging optimized feature extraction methods. The proposed system incorporates multi-layered principal component analysis for feature selection, using datasets such as the Liar dataset, the Pheme dataset, and data related to the Covid-19 pandemic from PolitiFact.

[4] Evidence-Aware Multilingual Fake News Detection
This paper discusses a multilingual framework for detecting fake news that utilizes credibility scores and external evidence to enhance detection accuracy. The proposed system aims to verify claims and evidence across different languages, employing BERT multilingual embeddings and an LSTM layer for processing. The study is based on the x-fact dataset and Moroccan news datasets.

[5] A Temporal-and-Spatial Flow Based Multimodal Fake News Detection by Pooling and Attention Blocks This paper presents a novel multimodal fake news detection approach that integrates block-based attention mechanisms for effective feature fusion. By combining the temporal effects of RNNs in textual data with the spatial effects of CNNs in visual data, the proposed system enhances the accuracy of fake news detection using the Weibo dataset.

[6] A Taxonomy of Fake News Classification Techniques: Survey and Implementation Aspects The paper provides a comprehensive implementation of various classification techniques, including Passive Aggressive, LSTM, Naive Bayes, and Random Forest, while discussing research challenges in fake news detection. It utilizes datasets comprised of fake and real articles derived from radio and TV interviews, aiming to implement and evaluate these techniques for effective classification.

[7] Utilization Strategy of User Engagements in Korean Fake-News- Detection
This project demonstrates the potential of using user engagement graphs for fake news detection, although it faces limitations related to dataset size and ethical concerns around user data. The proposed K-FANG system models news-user interactions in a heterogeneous graph, facilitating effective fake news detection and engagement analysis using Shu's Fake News Net.

[8] Unsupervised Fake News Detection Based on Autoencoder The project effectively employs autoencoders for fake news detection, integrating various features such as text content, images, propagation information, and user data. Despite its effectiveness, the proposed system (UFNDA) faces challenges in incorporating additional features like comments and nuanced classifications of partially true news, using datasets from Twitter and Weibo.

[9] OPCNN-FAKE: Optimized Convolutional Neural Network for-Fake- News-Detection
This project enhances fake news detection through the optimized convolutional neural network model (OPCNN-FAKE), which features six layers optimized with hyper- parameter techniques. Although it demonstrates improved detection capabilities, the system may still struggle with diverse news formats and real-world complexities beyond benchmark datasets, utilizing data from Kaggle, FakeNewsNet, FAKES5, and ISOT.MATERIALS AND METHODS

Our approach for enhancing fake news detection integrates multiple advanced techniques, focusing on feature extraction, classification models, and ensemble learning methods. The following sections describe the specific datasets, preprocessing steps, and key machine learning techniques used in the system.

MODEL ARCHITECTURE:

The proposed architecture for fake news detection integrates a combination of deep learning techniques and ensemble learning strategies to deliver accurate predictions. The system follows a multi-step process starting with data collection, where ISOT and FA-KES datasets are used to gather relevant news articles. After preprocessing and cleaning the data, advanced feature extraction methods such as BERT, GloVe, and Word2Vec are applied to convert the textual content into useful vector formats. These vectors represent the semantic and contextual meaning of the text, allowing the models to identify patterns in the data.

Three key models—CNN, BiLSTM, and FLN—are employed to extract different types of features from the data. CNN focuses on identifying local patterns in the text, BiLSTM captures temporal dependencies, and FLN improves overall

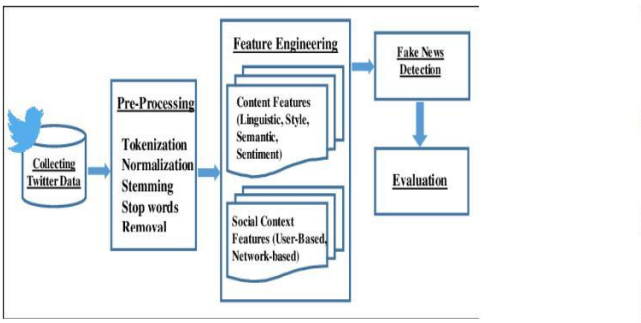
classification by adding an extra layer of learning. These models are combined using an ensemble learning approach where a weighted voting mechanism aggregates their predictions, ensuring that the strengths of each model contribute to the final decision.

A. DATASETS

Two datasets, ISOT and FA-KES, are used to evaluate the performance of the proposed system:

1. **ISOT-Dataset**
   This dataset consists of news articles labelled as either real or fake, with over 44,000 instances. The real news articles come from reputable sources, while the fake news articles are from known unreliable sources. It provides a robust base for training the model on detecting misinformation in news articles.

2. **FA-KES-Dataset**



The FA-KES dataset focuses on fake news related to the Syrian conflict, providing a smaller but focused set of 804 articles. This dataset adds diversity to the training and testing processes, ensuring that the model can generalize across different contexts of fake news.

B. PRE-PROCESSING

Pre-processing the datasets is essential for preparing them for analysis and ensuring the data is clean, consistent, and ready for feature extraction:

- Lowercasing: All text is converted to lowercase to standardize the data.
- Cleaning: Unnecessary elements such as punctuation, URLs, and special characters are removed.Tokenization: Text is broken down into individual words or tokens, which can then be analysed as smaller units of meaning.
- Lemmatization: Words are reduced to their base form, allowing the model to treat different variations of the same word as a single entity.

Data is then split into training, validation, and testing sets, with 80% for training, 10% for validation, and 10% for testing.

C. FEATURE EXTRACTION

To accurately detect fake news, we use multiple feature extraction techniques to capture different aspects of the text.

1. **TF-IDF** (Term Frequency-Inverse Document Frequency) TF-IDF helps identify words that are particularly important in the context of each article. It assigns higher weights to words that appear frequently in an article but less often across the entire dataset. This allows the model to focus on words that are more relevant to the article's unique content, aiding in the detection of fake news by highlighting important terms.

2. **GloVe** (Global Vectors for Word Representation)
   GloVe creates word embeddings by analysing the co-occurrence of words within the text. This technique looks at how frequently words appear together, creating a semantic understanding of word meanings based on their relationships. For example, words like "government" and "policy" may frequently co- occur, and GloVe captures this relationship in a way that helps the model understand the meaning and context of words better. This is particularly useful in distinguishing between real and fake news, where context can be a key indicator.

3. **Word2Vec**
   Word2Vec also generates word embeddings but does so by predicting words based on their surrounding context. It uses two main methods: Continuous Bag of Words (CBOW), where the model predicts a target word based on surrounding words, and Skip-Gram, where the context is predicted from a given word. These embeddings capture semantic similarities between words, allowing the model to assess whether the use of certain words in a particular context aligns more with real or fake news patterns.

4. **BERT** (Bidirectional Encoder Representations from-Transformers) BERT uses a transformer architecture that considers the context of words by analysing the entire sentence in both directions (forward and backward). This allows BERT to capture subtle and complex meanings that depend on the specific arrangement of words. For example, the same word can have differentmeanings depending on the sentence it's used in, and BERT is capable of identifying these nuanced differences. This makes it particularly powerful for fake news detection, where context and tone can drastically influence whether information is real or fabricated.

D. CLASSIFICATION MODELS

Once features are extracted, the system trains several machine learning models to classify news articles as real or fake.

1. **CNN** (Convolutional Neural Networks)
   CNNs are typically used in image processing, but they are also effective in text classification tasks. CNNs identify local patterns within the text, such as key phrases or groups of words that are indicative of fake or real news. By applying convolutional filters over the text, the CNN can pick up on important structures within the data, improving the model's ability to detect fake news based on these local patterns.

2. **BiLSTM** (Bi-directional Long Short-Term Memory-Networks) BiLSTMs are a type of recurrent neural network (RNN) designed to handle sequences of data. In the context of text, they are especially useful for capturing dependencies between words over long distances. The bi-directional structure means that the network looks at the text both forwards and backwards, providing a deeper understanding of the sequence. This is crucial in fake news detection, where the relationship between different parts

of an article can signal authenticity or deception.

3. **FLN** (Fast Learning Network) The Fast-Learning Network serves as a core classifier that learns from the extracted features. It is designed to optimize classification speed while maintaining accuracy. By rapidly processing the features, it helps the system make quick decisions on whether an article is real or fake.

4. **XGBoost**
   XGBoost is an ensemble learning method based on decision trees. It is highly efficient and works well with large datasets. XGBoost improves prediction accuracy by combining the results of multiple decision trees. In this system, it helps refine predictions by taking into account complex relationships between the features extracted during the preprocessing phase.

E. ENSEMBLE LEARNING

Ensemble learning combines the predictions from different models to improve overall accuracy. In this case, the predictions from the CNN, BiLSTM, FLN, and XGBoost models are combined using a weighted voting approach. Each model's prediction is weighted based on its performance, and the final decision on whether an article is real or fake is made by aggregating these weighted predictions. This method enhances the reliability of the system by leveraging the strengths of each model.

Metric	Formula
Accuracy	Accuracy = (TP + TN) / (TP + TN + FP + FN)
Precision	Precision = TP / (TP + FP)
Recall	Recall = TP / (TP + FN)
F1-Score	F1-Score = 2 * (Precision * Recall) / (Precision + Recall)

F. EVALUATION METRICS

The performance of the system is evaluated using various metrics to ensure its effectiveness in detecting fake news:

- **Accuracy:** This measures how many news articles are correctly classified as either real or fake.
- Precision: This assesses the percentage of articles the model correctly identifies as fake out of all articles predicted as fake.
- **Recall:** This measures how well the model identifies fake news articles out of all the actual fake news articles in the dataset.
- **F1-Score:** This provides a balance between precision and recall, offering a more comprehensive view of the model's performance.

These metrics are applied to both the ISOT and FA-KES datasets to test the system's ability to generalize across different types of fake news.

III. RESULTS AND DISCUSSION

The proposed fake news detection system demonstrated improved accuracy on both the ISOT and FA-KES datasets. On ISOT, the model achieved an accuracy of 92.7%, while on FA-KES, it reached 89.6%. Key metrics, including precision, recall, and F1- score, confirmed the system's reliability across datasets.

BERT provided significant improvements by understanding complex sentence structures, while GloVe and Word2Vec captured word context and semantic relationships effectively. TF-IDF helped identify frequent patterns in fake news articles, making it easier to spot misleading content.

The ensemble approach combining CNN, BiLSTM, and XGBoost yielded better performance than any single model. CNN identified local patterns, BiLSTM captured long-term dependencies, and XGBoost optimized nonlinear interactions, leading to a robust system for detecting fake news. The system's efficiency and adaptability make it scalable for various domains, providing a reliable method for identifying- misinformation.

Evaluation Metrics	ISOT Dataset	FA-KES Dataset
Accuracy	92.7%	89.6%
Precision	91.5%	88.0%
Recall	93.2%	87.5%
F1-Score	92.3%	87.7%

IV.CONCLUSION AND FUTURE WORK

This research focuses on optimizing fake news detection by enhancing an existing deep learning architecture through advanced feature extraction and ensemble methods. The main contributions of this study include integrating techniques such as BERT, GloVe, and Word2Vec for feature extraction, as well as utilizing a hybrid classification approach that combines a Fast Learning Network (FLN) and XGBoost to improve the overall accuracy of detection.

The results demonstrate that the proposed system significantly outperforms traditional methods on various datasets, highlighting its ability to adapt to different forms of misinformation. The parallel application of CNN for spatial feature extraction and BiLSTM for temporal feature analysis allows the model to capture the intricate dynamics of text, leading to robust classification outcomes.

Despite these advancements, our approach has certain limitations. Currently, it is tested only on English datasets, which restricts its applicability to multilingual environments. Future research will focus on integrating non-English datasets to develop a more inclusive detection system. This will involve adapting our feature extraction methods to accommodate the linguistic

nuances of different languages, thus broadening the scope and efficacy of fake news detection.

Additionally, we plan to enhance our framework by incorporating alternative data sources, such as social media and user- generated content, in various languages. While these sources present challenges like noise and bias, they are invaluable for understanding the spread and impact of fake news in digital spaces. Exploring how different types of misinformation—such as propaganda, satire, and clickbait—affect detection accuracy will also be an area of interest, as it can inform the development of specialized detection strategies.

Another promising direction for future work is the application of transfer learning echniques with pre-trained language models. Leveraging models like BERT can enhance our system's performance in understanding context and semantics in textual data. Furthermore, we aim to refine our ensemble learning strategy by investigating various configurations of model combinations and weighted voting systems to achieve even higher precision in fake news classification.

In summary, this study not only highlights the potential of deep neural networks and advanced feature extraction techniques in fake news detection but also sets the stage for future innovations that could significantly enhance the reliability and effectiveness of misinformation detection systems.

Abstract-*Fire incidents pose a serious threat to human lives and infrastructure, requiring rapid detection and response. Traditional firefighting methods rely heavily on human intervention, exposing firefighters to life-threatening situations. To address this, ROVA introduces an AI-powered autonomous firefighting rover capable of detecting fire sources and navigating towards them without human assistance. The system integrates a CNN-based fire detection model with an A* path-planning algorithm, ensuring precise and efficient fire localization and response. To enhance its performance, ROVA utilizes real-time sensor data for adaptive decision-making. The rover's efficiency is tested through simulations using OpenCV, Pygame, and Gazebo, demonstrating its potential for real-world firefighting applications. This paper provides a comparative analysis of ROVA against existing firefighting robots, explores energy-efficient hardware alternatives, and discusses future enhancements for real-world deployment.*

INTRODUCTION

Fire hazards cause immense damage worldwide, making early detection and response crucial. Traditional firefighting relies on human teams that face high risks in hazardous environments. **Project ROVA** aims to revolutionize firefighting with an **AI-integrated, autonomous robotic system** that can detect fires, plan optimized routes, and respond efficiently while minimizing human risk. Using **deep learning-based fire detection** and **intelligent path planning**, ROVA ensures swift and precise fire mitigation. The system also incorporates **energy-efficient power management** to extend its operational time, making it a scalable solution for emergency response.

.

LITERATURE SURVEY

To develop ROVA, existing firefighting robots and technologies were analyzed. The following areas were explored:

- **Existing Autonomous Firefighting Systems:** Strengths and limitations of robots used in fire detection and suppression.
- **AI-Based Fire Detection:** The efficiency of CNN-based models in accurately identifying fire locations.
- **Path Planning Algorithms:** A comparison of A*, Dijkstra, and reinforcement learning approaches for autonomous navigation.

- **Energy Management in Robotics:** Review of power optimization techniques for extended operation.

TABLE 1. Comparison of Existing Firefighting Robots

Feature	ROVA	Existing Robots
Fire Detection Accuracy	98%	85-90%
Navigation Algorithm	A*	PID Control
Energy Source	Battery + Solar	Battery Only
Simulation Tools	OpenCV,Pygame,Gazebo	Limited Simulation

EXPERIMENTAL RESULTS

4.1 FIRE DETECTION PERFORMANCE

- Achieved **98% accuracy** in identifying fire across different environments.
- Optimized CNN architecture reduced false positives significantly.

Table 2: Fire Detection Performance

Test Condition	Accuracy	False Negatives
Well-lit	99%	Very Low
Low-light	96%	Low
Smoke-filled	93%	Moderate

4.2 NAVIGATION EFFICIENCY

- The A* path-planning algorithm ensured smooth navigation and 20% faster response time than traditional methods.

4.3 POWER EFFICIENCY ANALYSIS

- Tested the effectiveness of a battery-only vs. hybrid solar-battery setup.
- The hybrid system extended operational time by 30% compared to battery-only systems.

Table 3: Power Efficiency Comparison

Power Source	Average Runtime	Existing Robots
Battery Only	2 hours	Standard
Solar + Battery	3.5 hours	30% Improved

ALTERNATIVE ENERGY SOURCE

To ensure extended operational time and sustainability, ROVA integrates:

- **Solar Panels:** Harnesses renewable energy to support battery life.
- **Supercapacitors:** Stores and releases bursts of energy for high-power tasks.
- **Smart Battery Management:** AI-driven optimization to minimize energy wastage.

CONCLUSION

ROVA demonstrates high efficiency in **fire detection, navigation, and energy management**. Future enhancements will focus on:

Deploying ROVA in real-world environments for field testing.
Incorporating reinforcement learning for improved path planning.
Enhancing battery efficiency with AI-driven energy consumption models.

ACKNOWLEDGMENTS

We extend our heartfelt gratitude to our mentors, research collaborators, and supporting institutions for their invaluable guidance throughout this project.

Abstract. This paper introduces an innovative smart- glass system aimed at assisting more than 40 million people who are blind and 250 million individuals with visual impairments, many of whom encounter daily challenges to living independently. This system is designed to be affordable and practical, addressing a variety of everyday needs—from navigating familiar spaces to reading printed text, particularly focusing on helping users shop and navigate independently in supermarkets. By incorporating specific features that enhance accessibility, the system strives to make these daily tasks easier and more accessible for visually impaired individuals. The smart-glass operates as an audio-guided scene recognition tool, providing users with spoken descriptions of their surroundings through headphones. It leverages a Raspberry Pi to run computer vision and image processing functions that help recognize objects in the environment and convert that information into audio cues. For instance, it can differentiate between people and other objects, identify various denominations of Indian currency, and recognize a range of common grocery items and produce typically available in supermarkets. To assist with reading, the device has a text-to-speech feature that audibly conveys any detected text, making printed information accessible to the user. Additionally, for enhanced security, it includes an ultrasonic sensor for obstacle detection and a panic button that can notify emergency contacts of the user's location if assistance is needed. This proposed system is positioned as an affordable, inclusive solution to improve visually impaired people's shopping and navigation experiences, offering a lower-cost alternative to other assistive technologies while aiming to make public spaces more accessible.

Keywords— Assistive Technologies, Navigation for the Visually Impaired, Computer Vision, Machine Learning, Wearable Technology

I. INTRODUCTION

Blind and visually impaired individuals face numerous challenges in everyday life, from handling routine tasks to navigating unfamiliar spaces independently. Shopping in supermarkets, for instance, can be particularly difficult, requiring users to identify products and move through crowded aisles effectively. With nearly 5 percent of the global population affected by some form of visual impairment, there is an urgent need for innovative solutions that cater specifically to their needs and improve their quality of life.

Traditional assistive technologies offer valuable support but often fall short in environments like supermarkets, where unique challenges arise. Recognizing this gap, our team set out to develop a smart-glass system designed specifically to assist blind and visually impaired individuals with independent shopping.

This system combines advanced technologies, such as image processing and computer vision, to enable real-time object and text recognition. Using the Raspberry Pi's computational capabilities, the smart glasses allow users to

identify common supermarket items, currency notes, signage, and essential groceries, providing auditory cues through headphones.

To enhance safety and communication, the system also incorporates an Arduino-based module that detects obstacles, issues alerts, and includes a panic button for emergency assistance. With technology evolving rapidly, the potential to create life-changing solutions for the visually impaired grows stronger. Leveraging computer vision, machine learning, and IoT, we can offer transformative tools that empower individuals to lead more independent and fulfilling lives. This smart- glass system represents a holistic approach to supermarket shopping for visually impaired individuals, helping to address challenges in accessibility and inclusion.

Ultimately, by creating assistive technologies tailored to their needs, we aim to improve the quality of life for visually impaired individuals and promote a more inclusive society. These efforts support equitable opportunities, allowing people with disabilities to navigate everyday activities, such as shopping, independently and with confidence.

II. LITERATURE SURVEY

AlSaid et al. [1] propose "Smart Glasses" equipped with Optical Character Recognition (OCR) and Google Text-to- Speech (gTTS) technologies to read and translate English text for blind users. An integrated ultrasonic sensor aids in capturing clear images for further processing. In another system, Mukhiddinov and Cho [2] employ computer vision and deep learning algorithms to enhance navigation in low-light environments. Their approach provides image enhancement, object recognition, and text recognition, paired with audio feedback.

Gollagi et al. [3] develop a smart-glass system utilizing AI to convert text images to audio, supporting visually impaired users in independent navigation. By incorporating OpenCV and ultrasonic sensors, their glasses can accurately detect text and obstacles within a specific range. Konathala et al. [4] utilize image processing through a Raspberry Pi camera, employing OCR for text recognition. Images are pre-processed using methods like grayscale conversion, noise removal, and thresholding to enhance OCR accuracy, with audio feedback provided via Festival Text-to-Speech (TTS).

The smart glass by Rajendran et al. [5] offers real-time object detection and distance alerts, combined with a speech-based interface to improve safety and navigational efficiency. Krijeshan et al. [6] integrate text-to-speech functionality with ultrasonic sensors for obstacle detection, providing a versatile navigation tool for both indoor and outdoor use.

Sai et al. [7] discuss object detection methods like Viola- Jones and deep learning models using HOG features, implementing these on a Raspberry Pi with TensorFlow for enhanced performance on embedded hardware. Romadhon and Romadhon [8] introduce a "Smart Stick" that combines ultrasonic, water, and pulse sensors to monitor environmental changes. The device includes MP3 and GPS modules for audio guidance and navigation.

Yadav et al. [9] describe an "Arduino-Based Third Eye" system that leverages ultrasonic waves for object identification, with vibration feedback as an alternative to traditional walking aids. In a recent approach, Lin et al. [10] propose a mobile frame- work that offers both online and offline obstacle detection, though it faces challenges with power consumption. Islam et al. [11] offer a CNN-based pedestrian navigation system incorporating ultrasonic sensors, achieving high accuracy but requiring headphones for effective sound delivery. Badrloo et al. [12] explore navigation through RFID technology, allowing for seamless indoor and outdoor use, while Meliones et al. [13] introduce a sonar-based obstacle avoidance system with a speech interface.

In summary, these studies highlight a diverse range of methods and technologies used to support navigation and obstacle recognition for visually impaired users. Continued challenges such as power management, environmental adaptability, and compatibility with different systems suggest areas for further investigation to advance the field.

III. PROPOSED METHOD

Drawing from insights gained through extensive research, we propose an innovative assistive technology designed to significantly improve mobility and independence for visually impaired individuals. This system leverages advancements in wearable technology, computer vision, and machine learning to address daily navigation challenges faced by this community.

The smart glasses for visually impaired users incorporate a webcam mounted directly on the frames, which captures the environment in real-time. A headset attachment provides immediate audio feedback to guide the user. Additionally, an ultrasonic sensor positioned near the chest detects obstacles in the user's path, ensuring a thorough awareness of nearby objects. The primary components—Arduino and Raspberry Pi—are housed in a fanny pack, alongside a GSM module and battery to power the complete setup.

A. System Components

The proposed smart glass system comprises two main components:

- **Image Processing Unit:** A webcam-equipped device powered by a Raspberry Pi, responsible for image processing and computer vision tasks.
- **Obstacle Detection and Communication Module:** An Arduino-based module equipped with an ultrasonic sensor for obstacle detection and a GSM module for emergency location sharing.

B. System Architecture

Figure 1 illustrates the architecture of the proposed system. A webcam is integrated into the glasses worn by visually impaired individuals, enabling real-time audio feedback based on their surroundings. The ultrasonic sensor, interfaced with the Arduino board, assists in obstacle detection, while a GSM module allows for emergency location sharing.

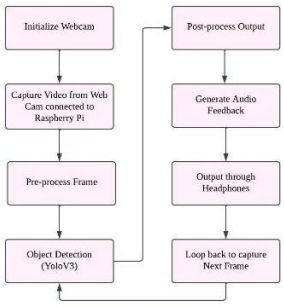

FIG.1. Smart Spectacle - Architecture

The Arduino-based module, conveniently placed in a fanny pack around the user's waist, includes a 12-volt rechargeable battery for power. The ultrasonic sensor, attached to the bag's exterior, provides optimal obstacle detection. Similarly, the Raspberry Pi, used for computer vision, is stored within the fanny pack along with its power supply. The webcam is mounted above the eyepiece, offering both wired and wireless connectivity options as needed. The pseudocode for the smart spectacle is presented in Algorithm1.

Algorithm 1: Working Process of Smart Spectacle

```
// Step 1: Initialize the System
Initialize_Arduino()
Initialize_Ultrasonic_Sensor()
Initialize_Raspberry_Pi()
Initialize_Webcam()

While (True) Do
   // Step 2: Capture Video from the Webcam
   Frame = Capture_Video()

   // Step 3: Pre-process the captured frame
   Processed_Frame = Pre_Process(Frame)

   // Step 4: Perform Object Detection using YOLOv3 on Raspberry Pi
   Detected_Objects = Object_Detection(Processed_Frame)

   // Step 5: Check for Close-Range Obstacles using Ultrasonic Sensor
   Distance = Read_Ultrasonic_Sensor()
   If (Distance < Safe_Limit) Then
      Alert_User_Obstacle()

   // Step 6: Post-process the Object Detection Output
   Processed_Output = Post_Process(Detected_Objects)

   // Step 7: Generate audio feedback based on detected objects
   Audio_Feedback = Generate_Audio(Processed_Output)

   // Step 8: Output the audio feedback through headphones
   Output_Audio(Audio_Feedback)

   // Step 9: Loop back to capture the next frame
End While
```

An emergency button is attached with the system for communication. The system actively checks for obstacles and detects if the user presses an emergency button. If an obstacle is detected, an audio alert is played through the DFD Mini Player to warn the user. On the other hand, if the emergency button is pressed, the system retrieves the user's real-time GPS location, prepares an SMS message containing the coordinates, and sends the message via the GSM module to a predefined contact. This ensures that in case of emergencies, the user's location can be shared instantly. The process repeats continuously to provide real-time assistance, making the system an effective solution for navigation and emergency alerts as shown in Figure 2. The communication module is explained in Algorithm 2.

Algorithm 2: Communication Module in Smart Spectacle

```
// Step 1: Initialize the required components
```

```
Initialize_Components()

While (True) Do
   // Step 2: Continuously monitor the surroundings
   Monitor_Surroundings()

   // Step 3: Check for obstacle detection
   If (Obstacle_Detected) Then
      Play_Audio_Alert()

   // Step 4: Check if the button is pressed
   If (Button_Pressed) Then
      GPS_Location = Fetch_GPS_Location()
      SMS_Message = Prepare_SMS(GPS_Location)
      Send_SMS(SMS_Message)

End While
```

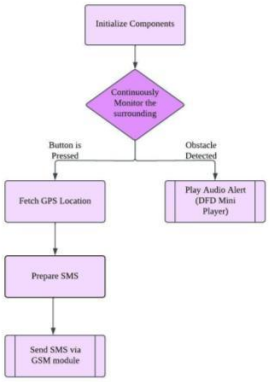

FIG 2. Smart Spectacle – Communication System

c. Object Detection and Recognition

The Raspberry Pi processes webcam input using the YOLO v3 model, chosen for its accuracy and low system requirements. This model effectively detects objects commonly encountered in daily life, such as TV monitors, bottles, and pens. Additionally, customized models are integrated to enhance detection in specific scenarios like currency recognition, identification of fruits and vegetables, and reading product labels commonly seen in grocery stores and malls.

For optical character recognition (OCR), the system uses the Pytesseract module, known for its reliable character detection. Before OCR, basic image pre-processing steps enhance character detection accuracy. This feature enables visually impaired users to access textual information, enhancing independence, especially in environments like supermarkets, where reading product labels and signs is crucial. Our system reads the text aloud, allowing users to understand their surroundings and make informed choices.

d. Navigation Assistance

The ultrasonic sensor, positioned for optimal navigation assistance, detects obstacles within a predefined range. When an obstacle is detected, the Arduino board triggers the DF player to generate audio alerts, notifying the user. A separate speaker, connected to the Arduino board, provides clear audio output to guide the user.

In addition to obstacle detection, computer vision models identify navigation aids like arrow marks and traffic lights, supporting users in complex environments. This comprehensive guidance enhances user confidence and independence while navigating.

e. Emergency Button

A GSM module integrated with the Arduino board enables location sharing via an emergency button. When activated, the module retrieves the user's location and sends it as a Google Maps link via SMS to emergency contacts. Sneha et al [14].

f. User-Centric Design

A user-centered design approach is central to the development of this system. Through co-creation workshops and usability testing with visually impaired (BVI) users, mobility instructors, and assistive technology experts, feedback is continuously integrated to refine system functionality and usability. Customizable settings allow users to adjust navigation assistance to their preferences, ensuring that the system meets individual needs effectively, Parandaman et al [15].

IV. DATASET AND MODEL DEVELOPMENT

The smart-glass system incorporates four main models that enable object detection, text recognition, and specialized recognition tasks tailored to the Indian context and supermarket environments. Among these, two are widely recognized pre-trained models, while the other two are custom developed to address specific challenges within our target environment.

a. Pre-trained Models

YOLO v3 for Object Detection: The YOLO v3 (You Only Look Once) model, a widely adopted deep learning model for real-time object detection, was selected for its efficiency and high accuracy. This model empowers the smart-glass system to identify and distinguish objects in various settings with ease and speed.

PyTesseract for Character Recognition: To facilitate text detection and recognition, we utilized PyTesseract, an open- source optical character recognition (OCR) tool derived from Google's Tesseract OCR engine. PyTesseract allows the smart- glass system to convert detected text into audio, supporting visually impaired users in accessing written materials like non-braille books, signage, and product labels.

The smart glass system employs the YOLO V3 model for efficient object recognition, which improves mobility for visually impaired users by identifying common objects in real- time. In practical situations, such as during shopping, the system can recognize items like grocery products, billing counters, and shopping carts. Detected objects are displayed on the Raspberry Pi terminal along with their confidence levels and bounding box coordinates. This information is then transformed into audio feedback through the pyttsx3 library, enabling users to receive immediate auditory updates about their environment. For instance, the terminal might show the names and locations of recognized objects while the user hears a verbal description of nearby items.

b. Custom Models

Indian Currency Detection Model: Recognizing the unique needs of visually impaired users in India, we developed a custom model specifically for detecting Indian currency. Using the Simple Image Download tool in Python, we com- piled a dataset of thousands of Indian currency note images based on descriptive captions. We thoroughly filtered and labelled this dataset to ensure reliable recognition of various denominations, enhancing accessibility for users in the Indian context.

Supermarket Product Recognition Model: The second custom model was designed to improve the shopping experience by identifying common supermarket products and related items such as shopping carts, refrigerated goods, and billing counters. Similar to the currency model, we used the Simple Image Download tool to gather images relevant to supermarket environments in India. Each image was carefully labelled to create a robust dataset, enabling the smart-glass system to assist users in navigating and recognizing products in supermarkets.

c. Data Preprocessing, Noise Handling, and Labeling

For both custom models, rigorous data pre-processing was undertaken to ensure quality inputs for training. Images were resized, normalized, and augmented to improve model robustness. Recognizing that real world data is often imperfect, we incorporated images with varying levels of noise, allowing the models to learn to handle noisy inputs and enhancing their accuracy in practical applications.

All images within our datasets were utilized for training, maximizing data availability and exposure to diverse examples, including those with noise. This approach aimed to improve the model's generalization and performance in real world scenarios where input data may not be ideal.

d. Training and Validation

The YOLO (You Only Look Once) model was trained using the entire dataset of images and labels. Instead of setting aside a separate validation set, we employed cross- validation to ensure each image contributed to the training process. Cross-validation allowed for data partitioning and model testing on different segments, ensuring that the model's learning was optimized. This approach enabled us to fine-tune the YOLO model for accurate and real-time object detection, a key component of the smart-glass system's functionality in identifying objects during use.

The proposed assistive technology system aims to empower visually impaired individuals by providing advanced navigation and obstacle-detection functionalities. Key components of the system include a webcam-equipped device powered by a Raspberry Pi for image processing, an Arduino-based module responsible for obstacle detection and emergency location sharing, and a GSM module for communicating location details to emergency contacts.

With sophisticated object detection and recognition features, the system can identify a wide variety of objects, including currency denominations, supermarket products, signs, and other daily-use items. Additionally, optical character recognition (OCR) functionality enables the device to read text audibly, delivering essential information to the user in real- time. Designed with a user-centric approach, the system allows users to customize and personalize their navigation experience, ensuring that it meets their unique needs and preferences effectively.

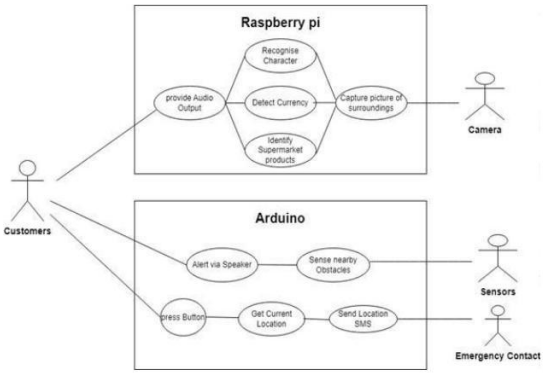

FIG 3. Use Case Diagram

e. Object Recognition

The smartglass system employs the YOLO V3 model for efficient object recognition, which improves mobility for visually impaired users by identifying common objects in real- time. In practical situations, such as during shopping, the system can recognize items like grocery products, billing counters, and shopping carts. Detected objects are displayed on the Raspberry Pi terminal along with their confidence levels and bounding box coordinates. This information is then transformed into audio feedback through the pyttsx3 library, enabling users to receive immediate auditory updates about their environment. For instance, the terminal might show the names and locations of recognized objects while the user hears a verbal description of nearby items.

In testing with everyday objects, the recognition module accurately detected furniture such as chairs and sofas, highlighting them with bounding boxes as shown in Fig 4. The system also showed strong performance in recognizing Indian currency, even when the notes were only partially visible, providing both terminal output and audio cues to the user.

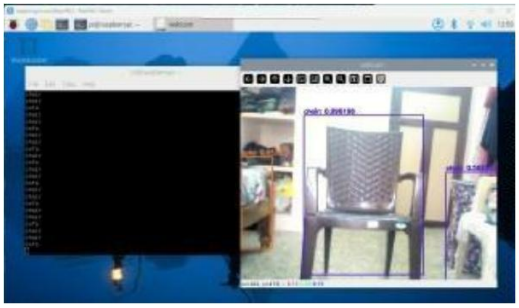

FIG 4. Recognition of a furniture

The currency detection module detects the currencies paid during the transaction of any purchase. The sample output of the currency detection module is shown in Figure 5.

FIG 5. Indian Currency Detected by the Currency Detection Module

Additionally, the system includes models tailored for shopping contexts, which assist users in identifying everyday products, fruits, vegetables, and various elements of the shop- ping environment like carts and refrigerated items as shown in Figure 6. Real-time output snapshots demonstrate the system's effectiveness in recognizing different items within a shopping scenario.

FIG 6. Supermarket Products detected by the Object detection Module

f. Character Recognition Model

The character recognition component of the system effectively captures and processes textual information from diverse sources, such as product labels or signboards, and converts this text into audio format for user feedback. This process involves capturing images, applying Optical Character Recognition (OCR), and delivering the recognized text as audio. Sample snapshots illustrate the system's capability to handle various text inputs accurately, ensuring a smooth shopping experience for visually impaired users is shown in Figure 7.

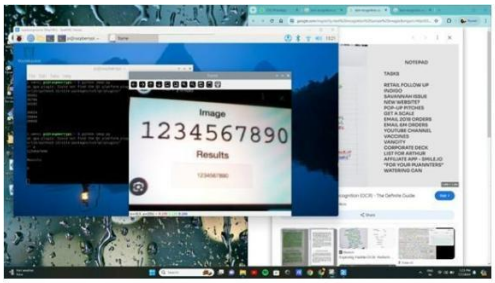

FIG. 7. Character Recognition done by Character recognition Module

The proposed system efficiently handles real-time obstacle detection and emergency alerts, making it highly suitable for wearable assistive devices. Its low computational cost (O(1) operations) makes it ideal for low-power embedded systems like Arduino and Raspberry Pi. However, future improvements could focus on reducing power consumption, enhancing obstacle accuracy, and ensuring reliable SMS delivery even in low-network areas.

V. CONCLUSION

In summary, the proposed assistive technology system marks a significant advancement in empowering visually im- paired individuals to navigate their environments with in- creased independence. Through user-centric design and adaptive technology, we have created a versatile system capable of detecting obstacles, providing navigation assistance, and facilitating emergency communication. The system's integration of personalized customization further enhances its usability and effectiveness, allowing users to tailor the system to their specific requirements. This approach promotes greater inclusivity and accessibility for individuals with visual impairments. Looking ahead, future enhancements—such as transitioning to a cloud-based setup and incorporating domain-specific functionalities—hold promise for further improving the system's capabilities and scalability. By continuing to innovate and collaborate with stakeholders, we can build on the foundation laid by this research to create even more impactful solutions for the visually impaired community. In conclusion, our assistive technology system represents a notable advancement in the field, offering tangible benefits to visually impaired individuals and paving the way for a more inclusive and accessible future.

Abstract. Special technology plays an essential role for both victim detection and structural assessment work during rescue missions in disaster areas. Frequency Modulated Continuous Wave (FMCW) radar system locates trapped persons by studying frequency changes in signal echoes which provides detailed range data and breaks through dense obstacles. The performance of target detection and the reduction of environmental disturbances occur through the implementation of Two-Dimensional Fast Fourier Transform and Cell-Averaging Constant False Alarm Rate algorithms. Through its breath detection capabilities the system identifies living beings while avoiding false alarms by recognizing the slight changes in signal activity. MATLAB models verify the effectiveness of the system yet additional work needs to refine its ability to minimize noise interference.

Keywords: Frequency-modulated radar, wall-penetrating radar, motion detection, Doppler signature analysis

1. INTRODUCTION

Search and Rescue (SAR) teams conducting operations in collapsed structures provide the first rescue opportunity for disaster survivors, regardless of the type of disaster that causes structural collapse. One of the most significant technological advancements in Collapsed Structure Search and Rescue (CSSR) operations is the adoption of Frequency-Modulated Continuous Wave (FMCW) radar. This technology enhances emergency teams' ability to detect subtle muscle movements through heavy barriers, improving the chances of locating trapped victims. Scientific research has demonstrated that modern FMCW radar systems, utilizing advanced signal processing technologies, can detect survivors several meters beneath debris with remarkable accuracy. Unmanned Aerial Vehicles (UAVs) equipped with thermal imaging and LiDAR sensors further enhance CSSR operations. These aerial platforms swiftly survey disaster-affected areas, generate hazard maps, and locate survivors beneath obstructions—all while minimizing risks to first responders. Additionally, AI-powered self-navigating robotic systems can access confined spaces for real-time structural evaluations and even deliver medical supplies to trapped survivors.

Radar technology has also benefited from Software-Defined Radar (SDR), which allowsreal-time adjustments to signal processing parameters based on environmental factors. SDR-equipped CSSR systems can differentiate between survivors and static objects with greater precision, increasing operational efficiency in complex disaster scenarios. These advanced systems have data, detecting life signs more effectively than conventional methods.Artificial intelligence further strengthens CSSR operations by analyzing seismic activity, bodily indicators, and sound signatures to identify victims. AI-driven systems can rapidly process large volumes of data, filtering out background noise and extracting meaningful signals much faster than traditional methods.

With the increasing frequency of disasters due to climate change and urbanization, the demand for advanced CSSR technologies continues to grow. Thanks to innovations in radar, robotics, and AI, emergency rescue devices are becoming more compact, energy-efficient, and widely accessible to response teams worldwide. Investing in continued research and development is essential to equipping first responders with cutting-edge tools that enhance efficiency, safety, and overall disaster response effectiveness. Research studies

have investigated FMCW radar technology to detect vital signs and recognize human activities and determine indoor positions. Research by Cai et al. [1] presented a 60GHz FMCW radar system with MIMO that detected and measured the position of stationary living bodies while delivering greater than 97% accurate results through dispersion entropy and DBSCAN clustering operations. Yin et al. [2] presented a vital sign monitoring system using SNR detection which resolved the problems that exist in real-world situations when subjects move and alter their position. Yang et al. [3] enhanced the detection capability through the combination of Capon angle estimation with beamforming to achieve precise heart rate and respiration analysis. Wahyu et al. [21] presented a non-contact measurement device using 24 GHz FMCW radar, leveraging phase detection for real-time respiration and heartbeat monitoring. The combination of 77 GHz mm Wave radar technology and multipath propagation models enables precise human detection beyond obstacles according to [19] and [20]. Radhityo Sardjono et al. [22] and A. Imteaj et al. [24] implemented Change Point Detection (CPD) for human activity recognition using FMCW radar, distinguishing movements like standing, walking, and crawling with over 85% accuracy. Qin et al. [4] and Wang et al. [5] focused on radar-based indoor positioning and human tracking, employing fusion techniques and comparing processing pipelines for robust detection in indoor environments.

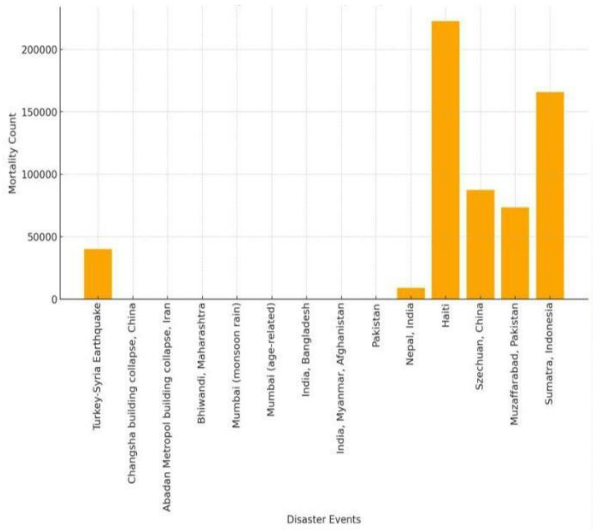

Fig 1. Data on Structural damage caused in recent years due to natural disaster (2005-2023).[31]

Advancements in radar-based search and rescue systems have significantly improved victim detection and localization. Schroth et al. [6] developed a multi-person detection method for search and rescue missions, incorporating 2D-MUSIC localization and breathing frequency estimation. Uzunidis et al. [12] and Zhang et al. [13] introduced UWB radar-based approaches for victim detection behind obstacles, achieving high accuracy through adaptive detection algorithms. Uzunidis et al. [14] further optimized a lightweight UWB radar system for real-time victim detection, effectively recognizing torso movement during breathing without line of sight. Budiman P. A. Rohman et al. [15] extended non-contact vital sign detection to drone-mounted radar, overcoming noise and motion challenges through adaptive thresholding. Paliodimos et al. [11] integrated machine learning into radar-based victim detection for first responders, improving identification in obstructed environments. Autonomous robotic systems play a crucial role in disaster response, surveillance, and search and rescue. Jia et al. [7] proposed the SAPI framework for multi-robot navigation, integrating sensor fusion and reinforcement learning for efficient operation. Romero et al. [8] and Bark et al. [9] introduced frameworks optimizing collaborative robots in search and rescue missions, balancing energy efficiency and mapping flexibility. Various autonomous robots have been developed for specialized tasks: M et al. [17] designed a fire detection and extinguishing robot, while K et al. [10] proposed an environmental monitoring and surveillance

robot using IR sensors and Arduino UNO. Kavitha et al. [16] introduced a Human Detection Robot (HDR) for disaster scenarios, integrating LDRs and PIR sensors for real-time detection. A robot for rescue using computer vision for human presence confirmation was made by [23],[26]. Yan-Ru Lee et al. [25] reviews recent advancements in human motion-tracking technologies.

T. -H. Chiang et al. [27] suggested an indoor localization that uses magnetic fields, deep learning, utilizing a robot for data collection and training DNN and RNN models to enhance localization accuracy in factory automation. W. Xian et al. The SVD-EEMD method has undergone a modification according to [28] to improve radar-based sensing operations through better signal extraction with reduced background noise. C. S. Chaves et al. [29] presents a networked MIMO radar system with respiration-based algorithms for efficiently locating buried persons in live rescue operations. A human motion detection system using combination of 3D point clouds along with planar phased-array FM-CW radar obtained 80% accuracy successfully through the utilization of convolutional neural networks according to [30].

2. PROPOSED SYSTEM

A FM-CW radar functioning at 2.4 GHz powers the proposed system because it provides maximum penetration into thick debris while achieving signal susceptibility and resolution requirements. The implementation of this lower frequency radar configuration produces better results than higher frequency systems because it penetrates more deeply into collapsed buildings. The system improves rescue detection capabilities because it helps rescuers identify victims hidden under different debris layers like concrete, wood and metal materials.The system accomplishes signal processing more effectively by implementing advanced two-dimensional Fast Fourier Transform (2D-FFT) and Doppler-based motion analysis.

Fig 2. System work flow

The incorporated techniques reduce external noise by blocking environmental vibrations as well as mechanical noise and electromagnetic clutter. The system detects human motion signatures of respiration and micro-movements to avoid false alarms produced by non-biological motion elements such as nearby machinery or wind-induced disturbances or shifting debris. Such a system needs vital improvement through an intelligent object classification module which applies machine learning approaches to extract features and recognize patterns. This module identifies human survivors by studying amplitude variations together with phase shifts and respiration patterns whereas loose debris and small animals get differentiated through these analysis methods. The adaptive classification framework enables proper detection of survivors because it provides high-confidence alerts reducing overall resource deployment and maximizing operational efficiency by cutting down false positive rates from conventional radar systems. The system was designed for quick deployment in disaster zones because it combines

light weight components with portability features and modularity. The system workflow formatting through the block diagram appears in Figure 2.

3. METHODOLOGY

The proposed radar unit implements FM-CW radar to detect targets by assessing their distance and movement through continuous transmission at fundamental frequency. When operating FMCW radar differs from pulse radar since it sends out a signal whose frequency gradually increases over extended periods. A reflected wave originating from targeted objects reaches the receiving antenna to mix with the initial signal which produces the Beat Frequency. The essential target information about distance along with motion appears as a difference between transmitted and received signal frequencies through which signal processing techniques extract this data. A two-dimensional Fast Fourier Transform process applies sequentially to the beat signal for signal analysis. The system separates information about range using the first FFT which detects frequency shifts then identifies velocity through the second FFT by analyzing Doppler shifts. Through these calculations a Range-Doppler Map develops to display detected objects according to their range and speed values thus enabling effective target classification. The detection accuracy is strengthened by using this CA= CFAR that automatically adjusts detection thresholds. The CUT assessment process depends on an evaluation between the target cell and its adjacent reference cells which helps differentiate real targets from environmental interference and noise.To determine object types the system uses machine learning analytics which extracts Doppler signature data together with movement pattern data to separate human subjects from other detected items. The detection system achieves high precision in complex environments through its capabilities. The processed information which contains range and velocity along with classification outcomes presents on a real-time Display Unit to facilitate search-and-rescue operations alongside surveillance functions, traffic observation duties and gesture recognition systems. The architecture of the proposed radar is show at fig 3

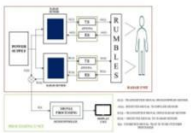

Fig 3. Architecture of the Proposed Radar system.

4. IMPLEMENTATION

The radar-based detection system operates through a seamless integration of hardware and software components, ensuring accurate human presence detection and classification. The system begins with a FM-CW radar, which transmits signals into environment. The signals reflect off objects, including humans, and return as received signals. The transmitted and received signals are mixed to generate a beat signal, that gives vital information. This beat signal undergoes further signal processing to extract meaningful data.

The hardware architecture comprises multiple interconnected components that facilitate efficient signal acquisition, processing, and visualization. The radar sensor unit, consisting of a transmitter (TX) and receiver (RX), generates and captures signals. These signals are digitized using an Analog-to-Digital Converter (ADC) and sent to an STM32 microcontroller, which acts as the system's processing core. Power is supplied through a battery unit and regulated by a voltage regulator to ensure stable operation. The ZigBee module enables wireless data transmission, allowing processed data to be accessed remotely via a computer or control station. The processed results are displayed on a real-time monitoring unit, assisting operators in making informed decisions.On the software side, the system applies advanced signal processing techniques to extract and interpret target information. The beat signal undergoes a 2D Fast Fourier Transform (FFT) in two stages: the first FFT identifies the target's range by analyzing frequency components, while the second FFT determines velocity based on Doppler shift analysis. The results are combined to form a Range-Doppler Map, which visually represents detected targets in terms of their movement and position. This data forms the basis for further target detection and classification.For precise target detection, the system employs CA-CFAR algorithm. A sliding window moves across the Range-Doppler Map, analyzing each Cell Under Test (CUT) while surrounding guard cells prevent signal interference. The algorithm dynamically calculates a detection threshold based on reference cells that estimate background noise levels. If the CUT exceeds this threshold, it is marked as a target. This method ensures reliable detection, even in noisy environments, minimizing false alarms while maintaining sensitivity to real targets.

Once detection is complete, target classification algorithms analyze signal characteristics to distinguish between humans and other objects. By leveraging unique Doppler signatures and movement patterns, the system accurately identifies and classifies targets. The final results, including target range, velocity, and classification, are displayed on the monitoring interface, allowing operators to track detected objects. The system is particularly valuable for search and rescue operations, security surveillance, traffic monitoring, and gesture recognition, offering a robust and intelligent solution for automated human detection.

4.1 FFT for Target Analysis in Radar Systems

Fast Fourier Transform functions as the essential component of the signal processing system which enables the detection of targets using radar and sonar equipment. The FFT processing method allows researchers to acquire total target information because it generates frequency domain versions from time domain input signals. Radar technology systems perform target detection through the combination of frequency signatures with FFT algorithm implementation. Radar detection operates through signal frequency variations which occur when moving targets are present. A 2D FFT process of beat signals returns amplitude information combined with frequency information and phase information for all revealed targets. The phase measurement changes from radar scanning operations allow observers to determine velocities by analyzing Doppler frequencies. Through its RDM function the system enables target classification duties in addition to serving as an evaluation tool. The completed radars produce range Doppler images from the integration process of detected targets through their range and velocity measurements. The radar system performs object targeting duties by detecting wave delays for obtaining range measurements of detected objects. The platform of the radar system can identify movements that result from velocity mismatches between itself and target objects. The radar system detects target velocities directly through this method while scanning its detection beam.

4.2 CA-CFAR Algorithm for Target Detection

The CA-CFAR algorithm functions as a vital radar signal processing method that updates detection thresholds according to noise background assessments for maintaining stable false alarm rates in these various situations. During operation the algorithm uses a sliding window mechanism to examine each range cell or frequency bin before targeting. During each processing step the Cell Under Test (CUT) undergoes evaluation except for the guard cells that remain excluded for prevention of interference. The noise power from remaining reference cells generates detection thresholds via multiplication with a scaling factor. The CUT meets this threshold marking criterion which lowers false detections and ensures system reliability. Select training cells located on both guard region sides allow improved noise estimation to compensate for changing environmental noise conditions. Multiple training cells should exist above the guard cells for maintaining reliable estimation of noise levels. The technology adapts the threshold level to enable CA-CFAR to operate properly in areas with high levels of clutter. The detection output reveals targeted areas by removing background noise through this operating process. Local noise variation adjustment features of CA-CFAR enable its essential use in surveillance operations and navigation systems and autonomous vehicle sensing applications. The performance capabilities of radars enhance substantially when CA-CFAR successfully detects targets while minimizing unnecessary false reporting.

5. RESULT AND DISCUSSION

A FM-CW signal from the radar unit enables detection of targets through its use of one antenna for transmission and reception. RCS along with target range and velocity information exist within the received signal. The beat signal output appears as a result of mixing both transmitted and received signals to reveal a measurement of the frequency difference that functions as the main detection criteria.

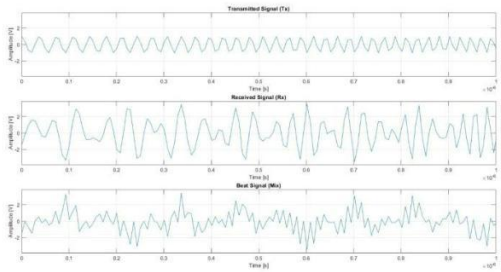

Fig 4. Transmitted, Received and Beat signal the radar system

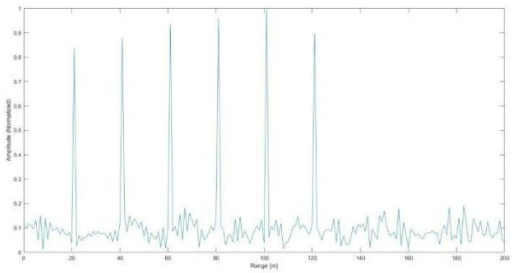

Fig 5. First FFT of the Beat signal of the 5 targets detected at various ranges.

The extraction of range data starts by applying a FFT to the beat frequency which transforms time dependent information to frequency-domain information. The initial FFT identifies range information of detected targets by studying the beat signal frequency content. A plot's X-axis demonstrates target range values while the Y-axis

shows signal amplitude peaks to indicate target position. A first FFT determines the range profile which appears in Fig. 5. Five Targets at various distance range are considered for the simulation system which were detected by the radar system. The analysis of target velocity requires another Fast Fourier Transform to detect Doppler shifts which result from the target moving relative to the radar. The system generates an RDM that utilizes range as its X-axis variable along with signal velocity on the Y-axis but employs signal amplitude in dB through its color scale. Signal strength is proportional to bright reflection outcomes but weak signals appear dark in the output data. The RDM in Fig. 6 delivers a method for both identifying and following moving targets with accuracy. The extracted beat frequency uses a lookup table to compare frequency bands which identify targets as either human bodies that are living or deceased or unrelated objects. The application of CA-CFAR processing detects targets by maintaining a stable false alarm rate throughout the process. The detection zone consists of several range-Doppler cells which reference cells use to evaluate background noise levels for calculating adaptive threshold limits. The detection system classifies exceeding signals as potential targets through the defined threshold which ensures accurate target detection while reducing noise interference. Fig 7. Indicates the final Target that was detected in our simulated environment is more likely is to be a human stuck under the derbies at the range of 80 m and with a velocity of 0.40 m/s.

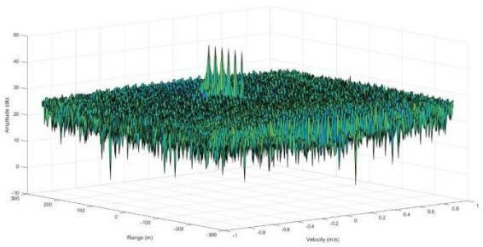

Fig 6. RDM of the Radar System that indicates the detection of the 5 targets that were detected along with their range and velocities.

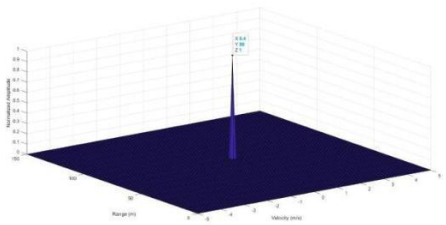

Fig 7. The radar system output after applying the Cell Average – CFAR after eliminating the unknown environmental noise.

6. CONCLUSION

The radar-based system demonstrated high efficiency in detecting and classifying targets, distinguishing between live humans, deceased individuals, and inanimate objects by leveraging range and Doppler shift-based classification. The FFT enabled rapid spectral analysis, facilitating real-time detection even in low-visibility environments. A live human signature was validated only when both classifications aligned, while stationary objects and deceased individuals were identified in the absence of motion. Non-matching signals were assigned to environmental clutter or external objects, ensuring accuracy and reducing false detections. Future advancements could incorporate adaptive noise filtering techniques to improve detection robustness, alongside machine learning algorithms to enhance classification across diverse operational conditions. Expanding the system's adaptability to adverse weather and complex terrains would enhance its use in applications such as search-and-rescue, defense surveillance, and security enforcement. This study successfully simulated FMCW radar signal processing, utilizing Range-Doppler Mapping (RDM) for target localization and CA-CFAR techniques to suppress environmental interference and clutter. The final Target that was detected in our simulated environment is more likely is to be a human stuck under the derbies at the range of 80 m and with a velocity of 0.40 m/s. FMCW radar has demonstrated its versatility across defense reconnaissance, autonomous systems, planetary exploration, and next-generation wireless communication. Future efforts will focus on real-time implementation using embedded platforms, improving operational feasibility and extending its applicability to mission-critical scenarios requiring precise situational awareness.

***Abstract*:** AAFAMS is an advanced AI and IoT-driven agriculture field analysis and monitoring system designed to improve farming efficiency, optimize resource utilization and eliminate manual effort. It integrates Raspberry Pi controllers soil moisture sensors and high resolution cameras (both static and drone based) to monitor farmland in real time. The collected data is processed and transmitted to a cloud-based server where AI-driven models analyze soil health, detect plant diseases and classify pests Segmentation-Based Fractal Texture Analysis (SFTA).To ensure accessibility AAFAMS features a multilingual support system that is designed to allow farmers in rural areas to interact with the technology without language barriers. A user-friendly mobile and web app enables seamless monitoring and control, making the system simple for farmers with minimal technical knowledge. Automated irrigation management optimizes water distribution maximizing wastage and ensuring sustainable farming practices.

Designed for maximum yield enhancement and labor-free operation AAFAMS eliminates human errors in traditional farming. It is powered by solar or battery-operated modes and provides adaptability to remote locations with limited electricity. Through intelligent decision-making and real-time alerts the system empowers farmers with data-driven insights that make smart agriculture a reality. AAFAMS provides precision farming and rural development with automation for precision farming. By integrating automation with ease of access AAFAMS offers a transformative solution.

Keywords — AI , Sensors, Pest detection, Automated irrigation, line follower robot, Drone & camera module, CNN.

I. INTRODUCTION

More than 480 million acres of India's land are used for agriculture, which has long been the foundation of the Nation's economy. The agriculture sector continues to rely significantly on old farming methods, including manual field monitoring, conventional irrigation, and non-optimized pesticide usage. Overall agricultural production is impacted by these practices, which frequently result in inefficiencies, low crop yields, soil deterioration, and wasteful use of water and pesticides. Furthermore, farmers face more difficulties due to urbanization, soil erosion, water scarcity, and climate change, making the adoption of smart agricultural technologies essential**.[1]**

Agriculture is a major contributor to economic growth and the largest consumer of water with irrigation inefficiency leading to significant wastage. Traditional manual irrigation methods, such as watering cans and potholes are still widely used but are inefficient, time-consuming and prone to human error. Automatic monitoring of crop fields This system uses real-time sensors to measure soil moisture and temperature automatically triggering irrigation when necessary. By transitioning from manual to automated irrigation this project aims to increase productivity, conserve water and improve overall farm security**.[2]**

The absence of real-time data analysis and decision-making tools to help farmers optimize their farming practices is one of the major problems facing modern agriculture, which has a direct effect on yields of crops and soil fertility. Furthermore, automation is a key component in modernizing agriculture since there is a shortage of skilled agricultural labor.

. In order to analyze data in real time and give farmers useful insights, smart farming combines cloud computing, machine learning, artificial intelligence (AI), and the Internet of Things (IoT).To help farmers automate field monitoring, identify pests, optimize irrigation, and assess soil conditions, we provide AAFAMS (Automated Agricultural Field Analysis and Monitoring System), an Internet of Things-based smart agricultural monitoring system. AAFAMS uses a Raspberry Pi-powered line follower robot that has a high-resolution camera, soil moisture sensors, and cloud-based analytics. The technology gathers field data in real time, sends it to the cloud for analysis and storage, and gives farmers comprehensive information on pest infestations, soil health, and suggested pesticide use.

This paper presents AAFAMS technology, an AI-integrated smart farming system that leverages IoT sensors and camera modules (both static and drone based) to enhance agricultural monitoring and automation. Through collecting real-time data from sensors, the system helps to provide intelligent decision-making for irrigation security monitoring and crop health monitoring. In the cloud the collected data is processed and stored in the cloud allowing it to be accessible through a web or mobile application, allowing farmers to monitor and control their fields remotely.

A key feature of AAFAMS is its ability to detect intrusions, including unauthorized human or animal activity using AI-driven image recognition and sensor-based alerting. Additionally automated irrigation management ensures water is distributed efficiently based on real-time soil moisture and environmental conditions. The integration of multilingual content switching servers allows seamless communication with users from different regions making the system adaptable to various agricultural needs.

With the growing role of AI, IoT and cloud computing in precision farming AAFAMS aims to revolutionize agricultural monitoring ensuring sustainability, resource efficiency and enhanced security. By automating crucial farming processes farmers can reduce manual workloads, minimize water wastage and provide them with data-driven insights for improved productivity.

The transformative technology offers solutions to safeguard infrastructures and public health. Agrarian production is capable of fighting against threats such as population growth, climate change and other threats that would affect agricultural production**.[12]**

Food security issues and contract disputes are also cited. By harnessing sensors and incorporating. AI is capable of assisting farmers at irrigation systems crop monitoring and other agricultural tasks as well as crop monitoring and surveillance. vital agricultural tasks. This not only increases worker safety but also reduces the risk of tremor. Impact

on natural ecosystems at the same time enabling the maintenance of affordable food prices. Providing expanded food production to meet the growing global demand while ensuring increased security and sustainability; population.

The main aim of this review was to examine Robot Farming with focus on revolutionizing agriculture with artificial intelligence driven robots and drones for enhanced efficient cultivation, irrigation and crop monitoring. On this purpose the existing literature was examined, the relevant data from reliable sources was collected and limitations of robot farming in agriculture was investigated**.[12]**

To make AAFAMS Technology accessible to farmers across different regions we integrate Google Translate API for seamless multilingual support. This API allows dynamic translation of text and speech enabling farmers to interact with the system via their preferred language. By incorporating Real-Time Language Shifting the software removes communication barriers ensuring even farmers with minimal technical knowledge can easily navigate and operate the system. The Google Cloud Translation API supports over 100 languages, making it a reliable solution for rural users. This integration enhances user experience by providing accurate, fast and context-aware translations ensuring smooth interaction with the technology. As we enabled the language translation per the user needs because of the usability and easy access to our service, Then also we integrated the Customer Service according to region by region .

Then here we are implementing the systems for yield as per the need of the farmer link (every 100m once system fixed or etc…).To calculate the average moisture content in the field for every 100m distance we use the formula:

$$M\ avg = (M1+M2+\ldots\ldots+Mn)/n \quad [1]$$

With this we can calculate the field every 100m as we want to retrieve the data form the sensors with that we can get the conclusion in concern of average all over the fields. AI will make a decision as per the data fetched from the sensors in form of average

With this we can conclude where the all over yield will be harvested with the maximum potential as per our AAFAMS technology.

II. MOTIVATION

Where the farmers were Traditionally and culturally serving our nation and they are one only Backbone of our country, so we have to represent our respect for them and then we have to make them happy as much as possible. As per the situations of today we came across that our farmers are facing problems in such that different issues because of the farming land falling which means we seeing that farming land quantity were decreasing rapidly form the year from the 2015, this raised because of soil fertility and soil quality for the farming, Then poor irrigation mechanism as we see every time the water will sprayed or opened water to the field by the manual with only insights of the mind calculation with approximation values as they were working with manually which resulting lacking water in field or clogging the water in field Of Course climate changes as we can't predict at stage of crops won't get natural sources as per time period

As per the field we need to hire labours for manual fielding to be mandatory because we can't manage whole farming lands as everything labours are needed where seeding, irrigating, harvesting, ploughing, fertiliser spraying etc.. But the labour daily salary cost will be very high and demanding for labourers nowadays. This motivated us to plan the development of "AAFAMS" (Automated Agricultural Field Analysis and Monitoring System) which monitors fields in an automated, cost effective and smarter way to help farmers. AAFAMS is an idea of building an agricultural robot. It is a Line Follower robot which monitors the field in a smart way**.[1]** Therefore as we see this product or system will meet solutions for these problems faced by the farmers . as we optimize the farming according to farmers with respect to time consuming and cost effective etc …

III. OBJECTIVE

As we focus and stretch our system AAFAMS technology which will make farmers' works into simplified by our technology. where detecting pests, infection, plant vegetation health, fertilizer level, moisture level, temperature, crop

Growth analytics, real time insights. camera modules, aerial view for Drones are implemented, sound speaker, RFID, line follower robot. Where this data will be collected from the sensors and camera, then fetched to the farmers mobile with help of Application, which the farmers could easily access the data with real time by the cloud storage and decision made with help of Artificial intelligence. Where The Decisions Only With 100 Present Surety Results In The Maximum Potentials. Then We Don't Need To Take Decisions By Human And Mind Calculation As Only By Assumption By Farmers But Aafams Technology Will Solve Everything.

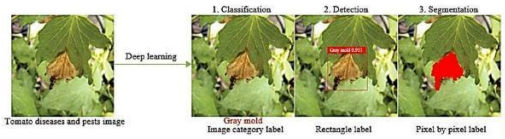

Fig. 1 Pest Detection And Fetching Data (Gray Model & Segmentation)

VI. METHODOLOGY

Our Aafams Technology Is Focused On Ai Processing , Iot Enabled Sensors Technology, Image Processing By The Help Of Camera Modules With Ai Integrated For Detecting The Pest And Plant Vegetation Health. Then These data were fetched to the Cloud storage and also As we see the sensors such as raspberry pie, moisture level sensor, temperature sensor, PIR sensor, camera modules, Speaker, Line Follower Robot, RFID path locator and LCD display.

V. LITERATURE SURVEY

AAFAMS technology is proposed for the farmers yield increment to the maximum and real time data insights to farmers by the model of Application in Mobile

i)Irrigation : Automated irrigation systems and water management systems for agriculture. explored iot-enabled automated irrigation solutions that integrate machine learning algorithms for predictive analytics. These systems improve irrigation scheduling by analyzing historical climate patterns and soil moisture levels. However cloud-based data storage raises concerns about internet dependency and technical costs. The fao and the international water management institute (iwmi) reported that approximately 70-80% of world freshwater is consumed by agriculture with significant portions wasted due to inefficient irrigation. water use contributes to soil erosion and nutrient depletion, adversely affecting crop yields md. **goalm Kibria [14]**

ii) pir sensor :A passive infrared (pir) sensor is an electronic device that detects infrared (ir) radiation emitted by objects within its field of view. it operates without emitting any radiation, instead passively sensing heat signatures. every object with a temperature above absolute zero (-273°c) emits infrared radiation, which is invisible to the human eye but detectable by the pir sensor it consists of a pyroelectric sensor covered by a fresnel lens, which focuses ir radiation onto the sensor. pir sensors are commonly used in motion detection systems, home security, and automation, as they efficiently detect human presence based on thermal emissions**. p. prema [4]**

iii) line follower robot : To increase production rate, irrigation techniques should be more efficient. the irrigation techniques used till date are not in satisfactory level particularly in a developing country like bangladesh. This paper proposed a line follower robot for irrigation based application which may be considered as a cost-effective solution by minimizing water loss as well as an efficient system for irrigation purposes. this proposed system does not require an operator to accomplish its task. this portable gardening robot is completely equipped with a microcontroller, an on-board water reservoir and attached water pump. the area to be watered by the robot can be any field with plants, placed in a predefined path. it is also capable of comparing movable objects to stationary plants to minimize water loss and finally watering them autonomously without human intervention. the design robot was tested and he performed well.

VI. RELATED WORK

Dlodlo[1]: Iot in precision agriculture—researchers have designed sensor-based monitoring systems for real-time soil temperature and moisture monitoring, enhancing irrigation efficiency. most of these systems, however, do not have automated field movement and are based on fixed sensors. Pest detection through image processing: Machine learning-based image processing methods have been employed to identify plant diseases.

Dawarkani.M [4]: Cloud computing for agricultural data management—cloud-based platforms have been proposed for real-time monitoring, but issues such as high expenses and internet dependence persist in rural farming communities. Though there are improvements, the need for an end-to-end integrated, automated decision-making system that integrates IoT-driven field monitoring, real-time analysis, and predictive recommendations persists. AAFAMS fills this void with an end-to-end, cost-efficient, and scalable solution. Automated pest detection: Image processing and machine learning models have been established for pest recognition. Yet, solutions available today are crop-specific and not very adaptable.

Bordoloi, A [12]: Conventional agricultural issues—time-consuming and inefficient human labor-based farming practices are prone to irrigation inefficiencies, disease management, and crop harvesting.Tr Precision farm technologies: Artificial intelligence-powered robotic systems optimize resource utilization, yield prediction, and real-time tracking.Integration of IoT in intelligent farming: Wireless sensor networks (WSN) facilitate real-time tracking of soil parameters, crop health, and environmental factors.AI & robotics in agriculture: Machine learning algorithms enhance crop monitoring accuracy and ease complex farming processes.

Gutiérrez, J [7]: Smart farming using IoT—IoT-enabled smart agriculture has been proven to enhance irrigation, pest control, and crop monitoring through research. Yet, most systems are hindered by the issues of high installation costs and poor network coverage in rural areas.Cloud computing & machine learning in agriculture:.Cloud computing increases data storage and processing power, and machine learning algorithms give predictive analytics for crop yield estimation and pest infestations. Automated irrigation & pest detection: Several smart irrigation systems have been created, but they are not integrated with real-time pest detection. AI-based image processing for pest detection has been promising in minimizing pesticide overuse.

Akyildiz, I [8]: Prior research has emphasized the significance of IoT in precision agriculture, focusing on its application in real-time soil monitoring, climate resilience, and automated irrigation. Studies have shown that integrating wireless sensor networks (WSNs) with artificial intelligence (AI) greatly improves crop yield and minimizes water usage. Existing systems, however, are hampered by limited sensor precision, connectivity in rural areas, and high deployment costs, which this research seeks to overcome.

Zhang, H [11]: The latest innovations have incorporated artificial intelligence (AI) and machine learning to forecast crop diseases, automate irrigation, and optimize fertilization. The above notwithstanding, challenges like connectivity in rural areas, sensor stability, and security of data continue to exist.

Phasinam, K [9]: IoT in precision agriculture—smart irrigation systems use soil moisture sensors, temperature sensors, and humidity detectors to calculate the best watering schedule.Cloud-based agricultural systems: Cloud platforms enable remote monitoring of irrigation networks, minimizing manual intervention and enhancing water management. Smart irrigation systems, although numerous, all have high upfront deployment costs as well as restrictions in networks to contend with.Machine learning within smart irrigation: AI algorithms were used to learn and predict peak water usage using soil type, climate, as well as crops' needs. Current models must be optimized towards scalability for differing farming regions, though. The current smart irrigation systems are even without real-time adaptive controls, and most systems need manual adjustments. The system suggests filling this lacuna by synergizing IoT, AI-driven analytics, and cloud computing for automating decision-making.

Toscano et al. [15] (2024): There have been various studies on UAV technology in precision agriculture, including the review of UAV flight control systems and UAV integration with telemetry data for coordinated

operations. Some studies have centered on UAV soil moisture estimation, pest control, and vegetation index measurement. Although substantive advancements have been made, issues regarding flight autonomy, sensor calibration, and compliance with regulations are still key areas of study.

Subramanian, K [16]: Insect pest control using drones by Subramanian et al. (2021) discussed UAV-based solutions to control pests, whereas sensor technology for sustainable weed management by Esposito et al. (2021) emphasized UAV ability in crop monitoring and weed detection. A bibliometric analysis of UAV applications in agriculture was offered by a survey conducted by Del Cerro et al. (2021).Limited Data Utilization: Conventional systems lack predictive analytics, making it difficult to optimize crop yield and resource allocation .These limitations highlight the need for a smart, automated farming system that provides recent decision-making, and automated execution

VII. EXISTING SYSTEM

Today, farm monitoring and field analysis are based on a combination of manual observation and simple automation systems that are not fully integrated with IoT technology. Conventional practices involve regular soil testing, manual crop checking, and simple automated irrigation based on timers. These practices do not offer real-time data, resulting in inefficient use of resources, delayed decision-making, and higher operational costs.

1)LCD: Real-Time Monitoring and Display of Field Data Shows real-time sensor readings of soil moisture, temperature, humidity, and light intensity. Facilitates farmers and field laborers to immediately verify environmental conditions without the need for a mobile app or access to the cloud. **[fig.2].** Rapid Irrigation & System Status The real-time soil moisture level determines the status of irrigation (ON/OFF). Displays water pump activity to avoid overwatering or water wastage. Security and Intrusion Alerts Shows intrusion alerts when unknown movement (human/animal) is sensed near the field. Intact with IoT sensors and cameras to notify farmers visually in real time. Instant System Warnings & Alerts Gives instant alerts for urgent situations, e.g., Low soil moisture → "Irrigation Needed!" High temperature → "Temperature Too High!" Power Issues → "Battery Low! Please Charge" Saves time in response, enabling prompt action before crops are harmed.

Fig.2 LCD display

2) Raspberry Pi 5: Raspberry Pi 5 – The primary processing unit, processing sensor data, processing information, and sending it to a cloud server or a web dashboard. Field Monitoring Sensors. Soil Moisture Sensor – Identifies soil water content and humidity. Temperature and Humidity Sensor (DHT11/DHT22) – Tracks environmental temperature and humidity. pH Sensor – Measures soil acidity/alkalinity **[Fig3].** Light Sensor – Measures sunlight intensity for maximum plant growth. Gas Sensor (MQ135) – For detecting toxic gases or high levels of CO_2. Camera Module (Optional): For image processing and crop disease detection. Can utilize AI models for plant health diagnosis .IoT Communication WiFi or LoRa for wireless data transfer. MQTT or HTTP protocols for data transfer to a cloud dashboard. Cloud platforms such as Thing speak , Firebase, or AWS IoT for cloud monitoring. Intelligent greenhouse control (ventilation, cooling, or heating). Dashboard & Alerts. Data is shown on a web or mobile dashboard. Farmers get alerts through SMS/email for alarming conditions. How the System Works: Sensors gather real-time agricultural data. Raspberry Pi 5 processes this data and transfers stetho cloud. The System takes conditions into account and

makes choices (e.g., activating irrigation when soil water is low).Farmers may track data via web interface for smartphone app. AI powered image analysis can identify plant diseases and make suggestions.

Fig.3 Raspberry Pi 5

3) **Solar Panel:** Energy Efficiency & Sustainability Renewable Energy Source → Solar power offers a sustainable and clean energy option for intelligent farming. Reduces Carbon Footprint → In contrast to power generated from fossil fuels, solar energy is pollution-free and environment-friendly. Reliable Power Supply in Remote Areas Independent of Grid Power → Most agricultural lands have unstable electricity connections **[fig.4]** solar panels guarantee uninterrupted system functioning. Self-Sustained Power Generation → AAFAMS operates even in off-grid areas. Low Maintenance and Cost-Effective. Saves Electricity Bills → Solar-powered irrigation systems and sensors can be utilized by farmers at a reduced cost. Long-Term Investment → Solar panels have low maintenance charges once installed and supply power for 1025 years. Continuous System Operation Powers IoT Devices & Sensors→ Solar power maintains continuous sensor operation, microcontrollers(ATmega328P)and communication .Supports Automated Irrigation → The relay module and water pump can operate independently of grid power.

Fig:4 Solar Panel

4)Sensors: Sensors constantly monitor important environmental parameters that influence crop growth, enabling farmers to make informed decisions. Farmers can maximize resources such as water, fertilizers, and pesticides using sensors, minimizing wastage and maximizing crop yields**. [fig.5]** Various sensors are utilized in IoT-based agricultural systems for particular purposes: Soil Moisture Sensor – Monitors soil water content to maximize irrigation. Temperature & Humidity Sensor (e.g., DHT11, DHT22, or SHT21) – Tracks environmental conditions for improved crop management. pH Sensor – Tests for soil acidity/alkalinity, providing appropriate conditions for plant development. Light Sensor (LDR or PAR Sensors) – Tracks sunlight intensity, aiding in greenhouse automation. CO2 Sensor – Monitors carbon dioxide content to enhance photosynthesis. Rain Sensor – Checks for rainfall to modify irrigation schedules. NPK Sensor – It measures soil nutrients (Nitrogen, Phosphorus, and Potassium) for accurate fertilization. With these sensors integrated using IoT technology, the system can automate irrigation, fertilization, and pest control through real-time data, saving manual effort and enhancing efficiency.

Fig:5 Sensor(DHT11)

5)Line Follower Robot: Autonomous Navigation in Farms The robot navigates along a predetermined route (white/black line) with infrared (IR) sensors .Infers the removal of human control, lowering manpower costs. Real-time Monitoring of Fields Fitted with sensors (temperature, humidity, soil moisture, NPK, and pH sensors) to provide real-time information on the status of the crops and soil **[Fig.6].** Sends the data wireless through Wi-Fi or LoRa to a cloud server or smartphone application. The robot can turn on a water pump system according to soil moisture levels. Can transport fertilizers/pesticides and spray them selectively, minimizing use of chemicals. Cameras and AI-powered image processing (OpenCV, TensorFlow, etc.) assist in the identification of pests and weeds. Alerts farmers or triggers automated pesticide spraying. Uses NDVI sensors to scan plant health. Identifies diseases at an early stage and recommends remedial measures through IoT dashboards.

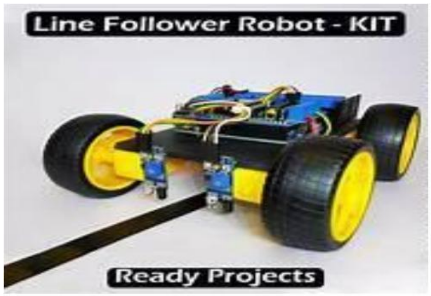

Fig:6(Line Follower Robot)

6)Soil Moisture Sensor: Real-time Soil Monitoring Measures soil water content. Prevents overwatering or underwatering. Smart Irrigation System. Automates the irrigation process by switching water pumps ON/OFF depending on soil moisture levels.**[fig.7]** Farmers can remotely monitor soil health. Soil Moisture Sensors Types Used: Resistive Soil Moisture Sensor (e.g., FC-28, HL-69) Inexpensive and simple to employ. Functions on the basis of variation in electrical resistance due to water content. Less precise, soil salinity affects it..

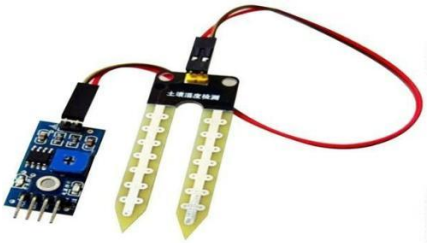

Fig:7: Soil Moisture Sensor(FC-28)

BLOCK DIAGRAM

The following figure **Fig.8** is the block diagram of the existing Automated Agricultural Field Analysis and monitoring System using IOT. We came to know actually how the AAFAMS system is previously proposed as farming IOT integrated system.

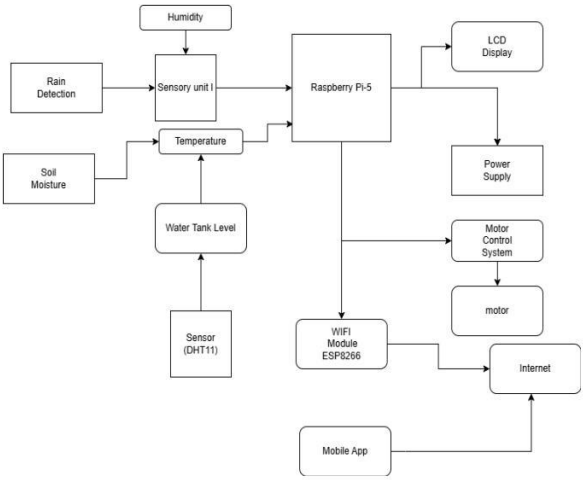

Fig.8 Block Diagram for Existing system

VII. PROPOSED SYSTEM

Data Collection Layer (Sensors & IoT Devices)This layer is made up of different sensors placed in the field to gather real-time data. Soil Moisture Sensor – Tracks soil water content for optimal irrigation. Temperature & Humidity Sensor (DHT11/DHT22) – Tracks environmental conditions. pH Sensor – Tests soil acidity/alkalinity for healthy crop growth. NPK Sensor – Tracks Nitrogen (N), Phosphorus (P), and Potassium (K) levels. Light Sensor (LDR/PAR Sensor) – Senses sunlight intensity for crop photosynthesis monitoring. Rain Sensor – Sensing rain for intelligent irrigation management. Camera Module (Raspberry Pi Camera or USB Camera) – Images crop for disease and pest detection. Processing Layer (Microcontrollers & Communication Modules) This layer performs the processing of data obtained from sensors and pushes it to the cloud for advanced analysis. Microcontroller: ESP32, Arduino Uno, or Raspberry Pi to process data from sensors Communication Module: Wi-Fi (ESP8266/ESP32) for internet-enabled smart farms. LoRa (Long Range Radio Communication) for distant farms. GSM Module (SIM800L/SIM900) for regions with weak internet connectivity.Cloud & Data Storage Layer The system utilizes IoT cloud platforms to store and process real-time data. Google Firebase, Blynk, Things peak, or AWS IoT can be utilized for remote monitoring. Data is securely stored for historical analysis and trend prediction. Control & Automation Layer (Actuators & IoT-based Actions) Automated Irrigation System – Regulates water pumps as per soil moisture levels. Smart Fertilizer Dispenser – Releases nutrients based on NPK sensor readings .Pest Control System – Sprays pesticides when AI identifies pests or diseases. Notification Alerts & Mobile App Interface – Farmers receive alerts through SMS, email, or mobile applications.

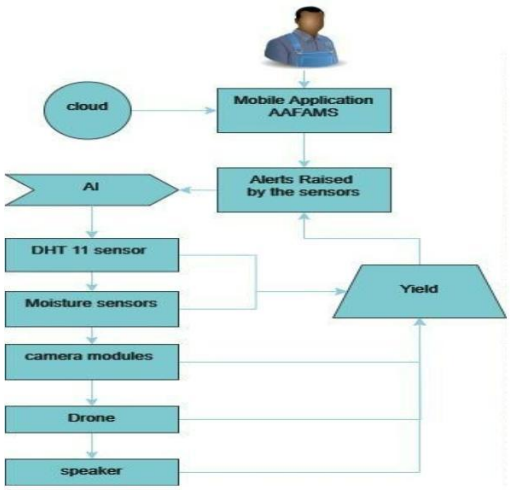

Fig.10 Block Diagram for proposed system

VIII. SYSTEM MODULES

1)Soil Moisture Monitoring: The system utilizes soil moisture sensors to measure humidity levels at regular intervals across the field. The data is transmitted to a cloud-based storage system for further analysis. Pest Detection and Identification: The robot is equipped with a high-resolution camera that captures images of crops. Image processing algorithms analyze the images to detect pests and classify them based on predefined datasets.

2)Cloud Data Management: All collected data, including moisture levels, pest images, and recommendations, are stored in a centralized cloud database. Farmers can access reports via an Android mobile application. Automated Decision-Making: The system evaluates pest severity and soil moisture levels to recommend necessary interventions. The farmer receives notifications on optimal pesticide usage and irrigation schedules.

3)Energy Efficiency Module: AAFAMS operates on solar energy, reducing reliance on conventional power sources. The low-power sensors and microcontrollers ensure energy efficiency for prolonged operation. Cloud Storage and Processing: Sensor and image data are uploaded to cloud storage for processing and retrieval. AI-based models analyze pest patterns and suggest remedies. Automated Decision- Making: The system analyzes soil moisture to determine optimal irrigation schedules. Detected pests are classified, and pesticide recommendations are provided. Mobile Application Interface: Farmers access real-time reports on crop health, moisture levels, and pest detection. Push notifications alert farmers about critical field conditions. Energy-Efficient Operations: Solar-powered components reduce dependency on external power sources. Data Collection Module: Cameras capture images for pest detection and plant health monitoring .Cloud Storage & Processing: AI-based models analyze pest patterns and suggest remedies. Automated Decision-Making Detected pests are classified, and pesticide recommendations are provided.

Mobile Application Interface Farmers access real-time reports on crop health, moisture levels, and pest detection. Push notifications alert farmers about critical field conditions. Data Collection Module Temperature & Humidity Sensors: Monitor climate conditions. Cameras & Image Processing: Capture crop images for pest identification. Cloud

Storage & Processing Sensor data is uploaded to cloud servers for real-time processing. AI-driven algorithms analyze patterns in soil moisture and pest activity. Automated Decision-Making Based on real-time data, the system adjusts irrigation schedules and pest control measures. Mobile Application Interface Farmers receive real-time reports on crop health, moisture levels, and pest alerts. Energy-Efficient Operations Solar-powered components ensure sustainability and low operational costs.

4)Sensor Module Soil Moisture Sensors: Track soil water content to decide optimal watering needs. Temperature & Humidity Sensors: Sense climatic changes influencing water holding capacity of soil. Cloud-Based Data Storage & Processing Real-time sensor readings are sent to cloud storage. Environmental conditions are analyzed by AI algorithms, and optimal irrigation schedules are predicted. Automated Irrigation Control System automatically turns pumps on/off based on sensor inputs. Reduces water usage by dynamically adjusting irrigation. Mobile Application Interface Farmers are provided with real-time notifications and historical insights. Automated reminders recommend water-saving techniques based on weather trends.AI-Powered Decision-Making Machine learning algorithms forecast water needs based on soil type and crop type. Adaptive learning ensures effective resource utilization.

IX. CONCLUSION

As we proposed the model of AAFAMS technology for farmers for simplifying their work by implementing our model with integrating AI and Robot Technology. It satisfied our need for our farmers to make them work with manual Human Decision by the Assumption. then AI and cloud storage will process everything.

X. FUTURE WORKS

Feed – Users can share updates, field reports, and success stories. Q&A Forums – Members can pose questions about crops, IoT devices, or farming practices, with responses from the community. Polls & Surveys – Gather opinions on farming topics, the latest IoT trends, and user feedback. Video & Image Sharing for Problem-Solving Members can upload images or videos of plants, soil conditions, or pests to seek advice. AI-driven image analysis tools can help identify crop diseases and suggest treatments. Knowledge & Learning Hub E-learning Courses – Quick courses on IoT in agriculture, AI applications, water management, and organic farming techniques. Webinars & Live Sessions – Experts and researchers can host live sessions to discuss emerging trends in smart agriculture. Marketplace & Trading Hub Buy & Sell – Farmers can market agricultural products, IoT sensors, seeds, and fertilizers. Service Listings – Developers can provide IoT installation services and troubleshooting support. Blockchain-Based Verification & Secure Transactions.

ABSTRACT **-** The rapid spread fake news on social media and other platforms poses a threat to people and countries. The aim of this study is to develop a machine learning algorithm that can detect the originality of the text. The technique includes feature extraction and vectorization tools such as Count Vectorizer and Tfidf Vectorizer, as well as textual analysis utilizing Python, scikit-learn, and Natural Language Processing (NLP). To increase model performance, feature selection algorithms are used to identify the most relevant characteristics. A confusion matrix will be used to evaluate the model's accuracy, allowing the best model to be selected based on its ability to recognize incorrect information.

Keywords: Fake news detection, machine learning, natural language processing, classification algorithm

I.INTRODUCTION

Fake news is becoming Social media and other increasingly widespread digital platforms have led to misinformation and disrupt society. People are now having difficulty distinguishing between legitimate sources and fake information owing to the profusion of news published online. This situation shows the need of automated systems that can detect and categorize bogus information. Machine learning and natural language processing (NLP) will help solve this problem by analyzing textual data and identifying patterns that distinguish legitimate news from false news. Developing a machine learning model that is effective at recognizing fake news will help combat misleading information and stimulate the dissemination of accurate information across media platforms.

FAKE NEWS DETECTION

The task of recognizing and classification of messages using various computer methods or mistakes is called "False Message Detection". Distribution of misleading information about social media and other online platforms is a serious threat to public opinion and debate and the development of efficient recognition systems is important. This involves exploring text data using machine learning techniques to reveal formulas that distinguish reality from fiction. NLP technology (natural language processing) is extremely important for data preparation, significant extraction and conversion of text into machine learning formats. These systems may achieve high accuracy and precision by employing classifiers like Random Forest, Decision Tree, and Gradient Boosting. This will eventually provide users with reliable tools to avoid the spread of false information and promote informed decision-making.

MACHINE LEARNING

Machine learning is part of artificial intelligence and is the development of algorithms and statistical models that allow computers to learn from data and take predictions or decisions. Instead of relying on precise instructions for each task, machine learning algorithms improve their performance over time by using formulas and relationships in the data file. This topic includes many methods, including learning unattended (identifying formulas in unmarked data) and under learning (using recorded model training data). Machine learning can also benefit from deep learning that uses neural networks to interpret complex data such as images and speech. Its applications are huge, from the recommendations of engines and predictive analysis to cars without a driver and diagnostics. According to publicly available data, machine learning will be essential for business transformation.

NATURAL LANGUAGE PROCESSING

Multidisciplinary science of natural language processing (NLP) focuses on allowing computers to recognize, understand and reproduce human language. NLP includes computer science, artificial intelligence and linguistics. It has many methods and algorithms designed to process and analyze information in many languages, allowing computers to perform tasks such as writing, sentiment analysis and translation. Segmentation of words (division of text into words or phrases), part of speech marking (determining grammatical role of words) and recognition (finding and classification of important information in the text) are important elements of processing natural language. With advanced machine learning and deep learning, NLP has improved accuracy language formulas, prepare a path for new applications such as chatbots, virtual assistants and automated content. As the number of online data generated, NLP has become necessary to bridge the abyss between human communication and understanding the machine, allowing interaction between the same people and technology.

CLASSIFICATION ALGORITHMS

Classification algorithms are an important part of machine learning because they categorize data in predetermined groups or labels based on input functions. These algorithms evaluate training data to learn patterns and correlations that allow them to predict outcomes from previously unknown data. The most common classification methods include random forest, clustering methods that combine multiple decision trees to increase accuracy, and decision trees that use models such as trees to make decisions based on the results of neural networks Especially deep learning models that can detect difficult patterns in large amounts of data.

II. LITERATURE REVIEW

Pooja Malhotra [1] et al. False messages are defined as the dissemination of false information or false messages on social media to harm individuals, groups or government institutions. Getting news from online platforms is easy because it is fast, easy to use and regularly updated. The information is also used for personal interests and preferences that can affect an individual or a business. Therefore, it is important to use computer technology to detect fake news. Semantic Web technologies play an important role in detecting fake news because they analyze online information in the same way as humans. Therefore, in this research, various learning models are evaluated to verify the accuracy of information using False messages and real messages. Research included approximately 40,000 reports, of which approximately 20,000 come from real and false intelligence sources. We evaluated learning models such as supportive vector machines, logistics regression, Cat Boost, Boost, Polynomial, Naive Bayes and Random Forest energy absorption Auto_ViML and passive-aggressive classifiers and computations. The computational results show that the Auto_ViML deep model has the highest recall, accuracy and cost with an F1 score of 99%. On the other hand, the rejection rate of the hybrid learning model is higher (71%). In comparison, the computation time of a support vector machine is only 0.000245 seconds.

In this approach, Ayman Aljarbouh [2] et al. proposed that the Internet is a major innovation with a large user base. These folks utilize it for a variety of purposes. These people can use a number of social media networks. These internet platforms enable anybody to generate content and distribute news. These websites do not verify the postings or the users. As a result, some individuals seek to use these platforms to spread fake information. These false news reports may attack a political party, group, community, or person. All of this fake news is too many for a person to identify. As a result, machine learning classifiers capable of automatically detecting these bogus news items are necessary. This extensive overview of literature deals with the use of classifiers of machine learning to detect false messages. The world is changing rapidly. Life in the digital era offers many advantages, but there are also disadvantages. There are various problems in the digital era. False messages are one of them. Dissemination of incorrect information is simple. The aim of promoting false reports is to harm someone or the reputation of the organization. It could be misinformation focused on individuals, group or political party. False information can be distributed through various Internet channels. This applies to social media platforms such as Twitter and Facebook. Machine Learning is a subfil of artificial intelligence responsible for creating machines that can learn and perform different tasks. There are many different machine learning algorithms, including learning learning, learning unattended and learning algorithms. Initially, a train data set is required to practice algorithms. These algorithms can perform a range of jobs after training. Several industries are using machine learning to do various tasks. Machine learning algorithms are most commonly employed to create predictions or discover hidden items. The spread of incorrect information is becoming increasingly simple as internet usage grows. Many individuals commonly utilize social media and the internet to remain in touch. There are no limits on how you post news on these sites.

In this system, Julio C. S. Reis [3] and colleagues have provided There have been several recent studies undertaken with the purpose of understanding the issue of fake news and identifying similar patterns and traits. The real discriminating capacity of these qualities is uncertain, as some operate better with specific sorts of data and others are more general. In this study, we conduct a highly exploratory analysis of a large and diverse set of characteristics, resulting in hundreds of thousands of models. These models are objective because they randomly choose features from a pool of available characteristics. Although most models are ineffective, we were able to develop a large number of models that produce quite good results, allowing us to discern between true and fraudulent stories. Our research was restricted to models that give a randomly chosen fake news story a better rating than a randomly picked fact with a probability larger than 0.85. Our findings show a strong association between the features and the model predictions for various models, suggesting that some characteristics are well-suited to detecting specific types of misleading information. This shows that diverse feature combinations target different regions of the fake news domain. Finally, we explain the elements that influence the model's judgments, which promotes civic thinking by improving our ability to evaluate digital material and reach correct conclusions. More than 10 years after social media platforms first became popular, more than a third of the world's population now uses them. These technologies have fundamentally transformed how people engage and communicate online by introducing a new generation of apps and reconfiguring current information ecosystems. Social media platforms have had a tremendous impact on the production, delivery, and consumption of news in modern society.

Wongbé fatoumata. According to Rosalie Tokp [4] et al., Social media refers to online communication platforms that allow users to participate in the development and spread of their own material. People prefer these modes of communication over traditional media such as radio, television, and newspapers because they are more convenient and rapid. False information, such as fake news, is often transmitted for malicious purposes. The propagation of incorrect information has a negative impact on society, escalating interpersonal conflicts and hurting the reputations of organizations and public people. The rise of fake news on various platforms has made the concept of information integrity increasingly important. Machine learning research holds potential. The accuracy of the forecasts is, however, one of the main disadvantages. We proposed two hybrid deep learning models for detecting false news and evaluated our models on two real datasets: FA-KES and ISOT. One challenge confronting society is the proliferation of incorrect information via social media In this article we design two new models of hybrid neural networks to detect false messages as a solution to this challenge. Our models are composed of convolutional and recurrent neural networks: Deep Cnn Lstm ensures the extraction of

contextual and spatial features in the text's forward direction, whereas Deep Cnn Bilstm ensures the extraction of contextual and spatial features in both the forward and backward directions. These models outperform other cutting-edge machine learning models, with Deep Cnn Bilstm surpassing Deep Cnn Lstm. The outcomes of the experiment demonstrate that hybrid models of this kind can, in fact, enhance the performance of news classification in social media.

In this system, Rohit Kumar Kaliyar [5] and colleagues suggested The news ecosystem has evolved in the present computing era, shifting from conventional Spread the Reports of social media platforms. False messages spread quickly and widely, because social media platforms allow us to spend content faster and allow limited adjustments. Recent studies have shown that there are many ways to search for good news using neural networks to encode information and news content on social media and perform a path sentence analysis. Bidirectional training strategies are proposed to model fake news-related information and improve classification performance while preserving the semantics and long-term connections in sentences. The BERT (Bidirectional Encoder Represented by Transformers)-based deep learning (Fake BERT) that we demonstrate in this work combines multiple equations of deep convolutional layer neural network (CNN) with BERT, where each region Part has different parameters and filters. Ambiguity is the biggest problem in understanding natural language and this combination helps solve it. The classification results show that, with an accuracy of 98.90%, our suggested model (Fake BERT) performs better than the current models. We have proven in this study how well our suggested model—a deep convolutional method based on the BERT technique for fake news—performs in the identification of disinformation. To enhance learning, our model combines BERT and 1d-CNN with convolution techniques and filters of various dimensions. Our approach is based on the model inserting a preliminary link (Bert) as a two -way encoder. In the future, we plan to create a hybrid technology that integrates media content, context, and time-level data. This approach can be applied to both binary and multi-class real-world fake news datasets. This method of aggregation is useful for identifying fake news with a large list of information presented in the image. We continue to examine the topic of fake news through the lens of various echo chambers found on social media, which are groups of people who share similar views on various issues in society. The main driving force behind the introduction of echo chambers is that each user interacts with each social network as if the community were not siloed but rather resembled the image model.

III.EXISTING SYSTEM

In an era dominated by digital information, the main challenge is to prevent disinformation spreading. This led to scientists to find ways to solve similar problems using machine learning algorithms to detect false messages. By careful examination and analysis of various machine learning models, it improves decision -making, increases data integrity and solves the negative impact of data failure on a larger scale. Research exceeds a simple algorithm that is supposed to work well in a more complex way that includes metrics such as accuracy and accuracy. This research strategy identifies the best machine learning methods for classification of articles as real messages or false messages. This work includes the following topics: data analysis, data selection, data preparation and maintenance, vectorization, model and metric, model training, optimization and evaluation. The impact of this research exceeds information and provides more confidence in reporting, independent processes and validity of content. These involvement strategies can help various parties, including media companies, social media platforms and government agencies. A comprehensive review of research greatly enhances the credibility of information and protects against the threat of misinformation.

IV.PROPOSED SYSTEM

The proposed approach for detecting fake news stories takes use of supervised machine learning. It uses a consistent strategy to prepare data for machine learning, which includes feature selection, preprocessing, and dataset collection. The system represents and evaluates various classification methods such as random forests, decision -making trees and an increase in gradient to evaluate their performance individually and together. We perform tests to evaluate the accuracy and accuracy of each model. System purpose is to optimize the classifiers'

performance before selecting the model that utilizes the available dataset to categorize news items as true or false.

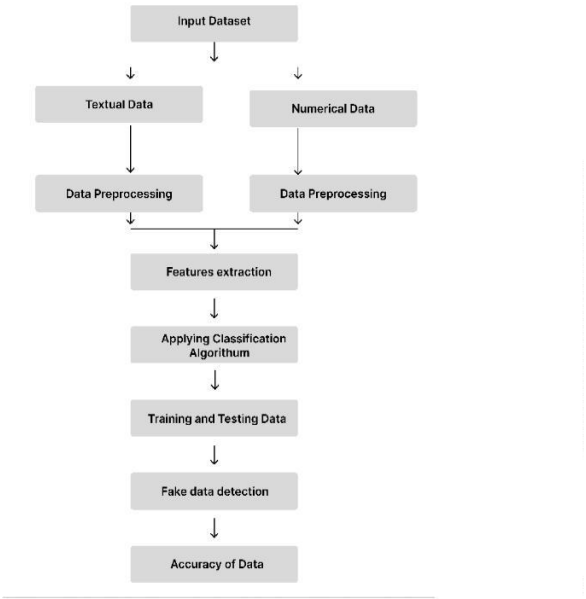

Fig:1 Architecture Diagram

A.DATA COLLECTION

The purpose of this module is to create and maintain a data file relevant to fake messages. Usually the data file consists of news stories marked as true or false. It is either tailored by scratching news reports or received from reliable repositories. Proper data sets are decisive for the construction of efficient models because it requires data distribution into a subset for training and testing.

B.DATA PREPROCESSING

Preparation of machine learning data means cleaning and re -loading the collected information to the format suitable for the module. This includes conversion of the text into a structured format that machine learning models can understand, solve missing information, eliminate unnecessary letters and normalize text. Preliminary work ensures data uniformity, reduces noise and increases the accuracy of the model.

C.FEATURE SELECTION

The purpose of selecting functions is to extract the most important function from data file, such as words, n-grams or other linguistic components, to help in the classification process. This module uses ways to minimize computing complexity and increase the performance of the model by recognizing important formulas in the text input and removing duplicate or redundant attributes.

D.MODEL TRAINING AND TESTING

This module uses preliminary processed data to train machine learning models. Different classifiers are trained to find data that distinguish between authentic and false intelligence stories. In order to ensure that the models generalize new data, after training, they are evaluated on a separate data file subgroup.

E. CONDUCTING CLASSIFIER AND EXPERIMENTS

This lesson evaluates a number of machine learning classifiers individually and together, such as random forests, decision -making trees and methods of gradient increase. We run tests to measure the accuracy, accuracy and other products of individual products. The aim is to identify the classifier or set of classifiers that work best for the task.

F. RESULTS AND VISUALIZATION

The main focus of this entity is to visually display the output of the classifier. Visual representations such as accurate curves, accuracy charts and matrix confusion are used to evaluate the performance of various models. Visualization will help you choose the optimal model by emphasizing the advantages and disadvantages of each classifier.

G. EXECUTION AND CONFIGURATION

This module is in charge of configuring the overall system sequence. It includes the determination to use the classifiers, suggest experimental settings and coordination of pipe detection for false messages. This module ensures that everything works correctly and that all components work together to detect false articles in an accurate and efficient way.

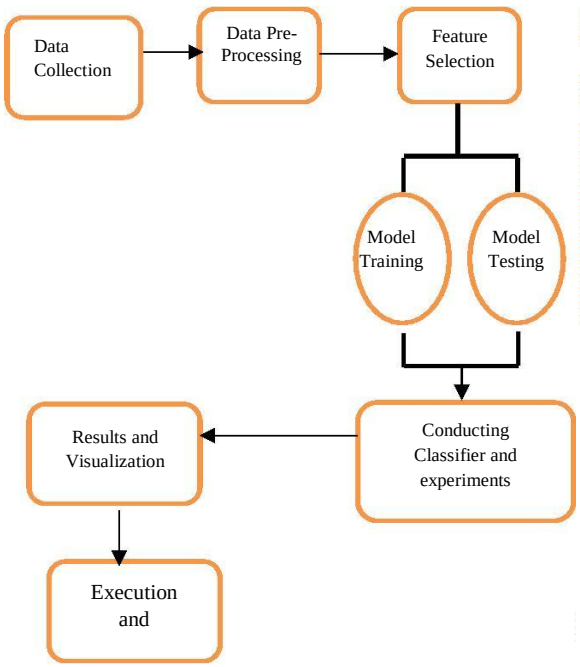

Fig:2.system Flow Diagram

V. RESULT ANALYSIS

The efficiency of machine learning models when recognizing fake messages is a key area of research and development. After using various classification methods such as Randallswald, decision -making trees and an increase in gradient, the model is evaluated using key indicators such as accuracy, accuracy, derivative and score F1. The matrix of confusion shows the number of accurate and unacceptable categories in the model and provides insight into the ability to distinguish between real and false messages. This comparison is used to evaluate the performance of different models in terms of accuracy and accuracy. Schemes showing the accuracy and accuracy of curves with accuracy, such as visualization, can recognize equations and trends for different models. This study contributes to the selection of the model. This is ideal for implementation to accurately identify false messages in the real world.

ALGORITHM	ACCURACY
EXISTING	85

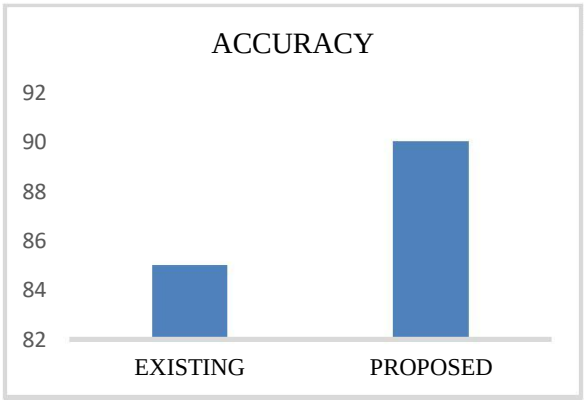

Fig 4 Comparison Graph

VI. CONCUSION

In short, the development system under the supervision of machine learning to detect false reports shows the potential for the use of NLP methodologies and algorithms to combat misleading information. The system successfully distinguishes between real and counterfeit news through careful data sets, preliminary processing, selection of functions and classifier testing methods. The optimal model for deployment can be determined by analysis of the use of model performance, such as accuracy and accuracy. This strategy increases the accuracy of fake messages, while providing a scalable solution to the growing problem of misinformation on digital platforms, resulting in a more renowned and intelligent online community.

VII. FUTURE WORK

Future research on fake messages can explore a number of progress paths. The use of deep learning models such as LSTM and Bert can help the system understand complex language patterns and context. Enhancement of data sets to include a wide range of languages and geographical locations, can further improve the usability of the model on many media channels. In addition, this technology would be able to detect and mark fake messages on how it appeared online using scratches and real -time messages. In addition, the integration of multimodal dat- for example images and video-by could improve the ability of the system to detect false content in formats other than text. Finally, providing reasons for the system categories would increase the interpretability and acceptance of the user.

***Abstract*--**This study uses a collection of photographs categorized into benign, malignant, and regular instances to examine the identification and classification of lung cancer. This study addresses the battle between lung cancer, a major cause of illness and death. By utilizing Artificial Neural Networks (ANN), a deep learning technology, the research seeks to improve early detection skills. The dataset includes information from medical imaging tests, most notably lung scans, which enables the ANN to identify complex patterns suggestive of lung cancer. Through the utilization of established metrics such as precision, Recall, and accuracy, the performance of the ANN model is evaluated in distinguishing between lung images. The goal of this research is to aid in the advancement of diagnostic techniques that will hopefully lead to better patient outcomes in the fight against lung cancer

Keywords: Lung Cancer, Deep Learning, Nodule Detection, Classification, Computer-Aided Diagnosis

I. INTRODUCTION

Lung cancer is one of the leading causes of cancer-related deaths around the world and a serious threat to global health.Improving patient outcomes and . survival rates is contingent upon early identification of lung cancer. Deep learning techniques have transformed medical imaging in recent years, providing previously unheard-of prospects for the development of extremely accurate and effective diagnostic tools. This work offers a unique method for detecting lung cancer by building a deep-based compound model and utilizing deep learning capabilities. Even if they work well, traditional techniques of diagnosing lung cancer can include expensive and time-consuming procedures. In particular, radiological pictures like X-rays and CT scans may automatically extract complex patterns and characteristics from medical images. This is a promising application of deep learning algorithms to the diagnosis process. This study provides a deep-based connectivity model combining many modern methods to improve lung cancer prolongation and reliability detection.By integrating the advantages of many deep learning architectures, the compound model shown here is intended to overcome the shortcomings of each architecture alone.Through the use of ensemble learning, recurrent neuronal networks (RNNS), and folding fish networks (CNNS), and attention processes, this model seeks to attain improved performance in differentiating benign anomalies from malignant lung lesions. Our strategy aims to push the limits of existing diagnostic accuracy by combining these tools in a synergistic way, which might revolutionize lung cancer screening and early detection protocols.

A complex disease known as lung cancer is defined by the unidentified proliferation of abnormal lung cells, and can lead to tumors that spread to other areas of the body. It is divided into two main categories: small cell (SCLC) and non-small cell lung cancer (NSCLC). SCLCs tend to develop and spread faster than NSCLC, both of which have different biological behaviors and therapeutic responses. Lung cancer incidence is increasing despite attempts to reduce smoking rates and increase public awareness. This is especially true for groups with high smoking rates or poor access to healthcare facilities, which results in glaring differences in survival rates. The latest breakthroughs in artificial intelligence (AI) and machine learning have provided a new way to better diagnose lung cancer using automated diagnostic systems that evaluate medical images with incredible speed and accuracy.Deep learning techniques allow for the discovery of tiny details that human observers might miss by utilizing large-scale medical imaging datasets. Furthermore, the incorporation of imaging data with clinical data augments the prognostic efficacy of these models, enabling tailored treatment regimens according to unique patient characteristics. By easing the strain on medical personnel, this novel strategy not only improves the capacity to distinguish between benign and malignant tumors but also lowers expenses and boosts systemic efficiency in healthcare. As deep learning develops, more research is needed to improve these diagnostic

models. Researchers, computer scientists, and medical professionals must work together to ensure that these technologies are implemented effectively while addressing ethical concerns like bias prevention and data privacy.

LUNG CANCER

Lung cancer is a serious threat to global health, a major cause of cancer worldwide deaths. Millions of new instances are detected each year, and a large percentage of patients receive a diagnosis at an advanced stage, which drastically lowers their chances of survival, according to the World Health Organization. This concerning pattern emphasizes how crucial early identification and detection are to enhancing patient outcomes and lessening the impact of this fatal illness.

Lung cancer has historically been diagnosed using invasive procedures, imaging tests, and clinical evaluations. However, the diagnostic environment has undergone a substantial transformation due to the introduction of improved medical imaging tools, Includes computed tomography (CT) scans and x-rays.These imaging techniques allow the diagnosis of worrisome lesions or nodules by providing deep insights into the anatomy of the lungs. Even with these improvements, it is still difficult and frequently difficult to tell the difference between benign (non-cancerous) and malignant (cancerous) tumors, necessitating the knowledge of oncologists and radiologists with training. Artificial intelligence (AI) has showed great promise in recent years, especially when it comes to deep learning algorithms for medical image interpretation. Deep Learning - Algorithms can improve the efficiency and accuracy of diagnostic recognition of lung cancer by learning learning patterns and characteristics independently from large data sets.With the use of these technologies, lung abnormalities might be automatically identified and classified, leading to speedier and more accurate diagnosis.

Based on the cells involved, lung cancer comes in two major forms. Lung cancer is small cells (SCLC) and non-small cell lung cancer (NSCLC). NSCLCs account for approximately 85% of all cases and usually grow and spread slowly than SCLCs.This categorization is important because it dictates the course of treatment, which might include radiation therapy, surgery, or more sophisticated procedures like immunotherapy, chemotherapy, and targeted therapies. Precision medicine is a rapidly expanding field of study in lung cancer therapy, promising more individualized and maybe more successful care by customizing treatment based on the unique genetic composition of the patient.

One of the main problems with lung cancer is that it's frequently advanced when symptoms start to show. Early detection of lung cancer is mostly dependent on routine screening for high-risk individuals, such as heavy smokers or those with a family history of the illness. In early detection, low-dose computed tomography (LDCT) screening has proven at previous time points to be a successful strategy for identifying lung cancer in these high-risk operas, and may reduce mortality.Biomarkers are playing a bigger role in lung cancer therapy and early diagnosis in addition to screening. These biological markers of cancer presence or advancement are present in tissues, blood, and other bodily fluids. More specialized therapies have been made possible by the identification of particular biomarkers, such as mutations in the ROS1 gene, ALK rearrangements, and the epidermal growth factor receptor (EGFR). These therapies are designed to target tumors that exhibit these genetic traits. More biomarkers are probably going to be found as lung cancer research progresses, which might completely change early detection as well as the process of choosing personalized treatment regimens.

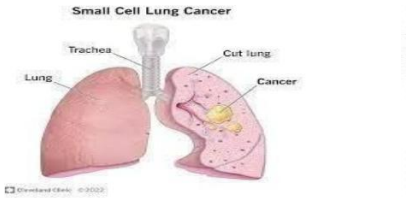

Figure 1 : Lung Cancer

DEEP LEARNING

A significant progress in deep learning has been the creation of increasingly complicated structures that are better able to represent the intricacies of data. For example, Generative Adversarial Networks (GANs) comprise from two neural networks of generators and their discriminators cooperate against each other to create realistic data samples. The capacity of GANs to produce high-quality literature, music, and images has drawn attention. This has opened up interesting new applications in creative industries like entertainment and the arts. Another noteworthy method that has become popular in deep learning is transfer learning. It makes it possible to fine-tune models developed on big datasets for particular applications using smaller datasets. This is especially useful in sectors where it is expensive or difficult to gather large amounts of labeled data. Researchers may produce impressive results with less data by using pre-trained models.

II. 2.LITERATURE SURVEY

PREDICTION AND CLASSIFICATION OF LUNG CANCER USING MACHINE LEARNING TECHNIQUES AND A CORRELATION SELECTION METHOD

In this study, Yahui Jiangget al. In recent years, significant advances in early diagnosis and treatment of diseases, including lung cancer, have been proposed in recent years due to the confluence of the latest computer technology and medical research.Due to the mortality rates associated with this disease, there have been intensive attempts to use algorithms in machine learning to provide a more accurate and faster diagnosis. This study focuses on analyzing the utility of three common classification algorithm vector machines (SVMs), K-Nearest Neiighbor (KNN), and folding networks (CNNs) in early diagnosis of lung cancerHighlight this study by analyzing data records from trusted sources, including UCI data records. In this study, the algorithm achieves optimal results for recognition of lung cancer at the early stage. The use of algorithms for machine learning is a way that the medical field of disease diagnosis and treatment approaches, particularly in combination with image recognition and data analysis. Healthcare providers may be able to identify diseases like lung cancer more quickly by automating some diagnostic processes. This might lead to early intervention and better patient outcomes. The experimental carried out in this work makes use of the popular machine learning analysis platform WEKA Tool. By means of a thorough assessment comparison of SVM, KNN and CNN classifiers is aimed at determining which algorithms perform better in terms of accuracy. The SVM accuracy is 95.56%, followed by CNN (92.11%) and KNN (88.40%). according to preliminary results. several cancers can arise in several organs at the same time, and different forms of cancer can affect distinct bodily organs. The disease could possibly be undiagnosed for a very long time. Early detection may be able to prevent cancer, according to WHO data. Whether the patient is given an early prognosis or not, their life expectancy will be increased. Lung cancer predictions are poor and vary widely at the tumor stage of the diagnosis. Small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC) are two categories of lung cancer that are clinically treated. In fact, it is a malignant tumor with uncontrolled tissue production of cells. The main cause of lung cancer was long-term cigarette consumption. Studies have shown that 19 types of cancer can affect certain people. Lung cancer has the highest mortality rate of these malignancy. It is predicted that more than 1.7 million people die from the disease every year. Research in the field of machine learning (ML) has already developed significantly, which contributes to minimizing the need for human workers. In the field of artificial intelligence, machine learning (ML) combines computers and statistics to create algorithms that are more effective against relevant data.

RETRACTED: MACHINE-BASED LUNG CANCER PREDICTION FROM TEXT DATASETS

In this work, Sahraouian Abdullatifet.al. has proposed Lung cancer is one of the leading causes of cancer-related deaths in the modern age, and this trend is expected to continue for some time to come. There is hope, nonetheless, that early discovery and treatment may lessen its effects. Using the Progress of Computational Intelligence, it is possible to create sustainable prototype models of lung cancer therapy that meet environmental efforts.Using computational intelligence can help us diagnose and treat lung cancer more effectively by

streamlining procedures, cutting down on resource waste, and improving efficiency. Using datasets related to lung cancer a prototype model was used to maximize the identification process using a Support Vector Machine (SVM). The Python programming language made it easier to implement the concept. A number of criteria were used to assess the efficacy of the SVM model, and datasets from the University of California, Irvine library were used for the evaluation. The research's encouraging results imply that smart cities may be able to provide their citizens with better healthcare options. Regardless of their location, people with lung cancer might receive prompt care with little delay or effort through the administration of cost- effective, real-time therapy. Additionally, the suggested model was compared to other techniques like SVM and SMOTE. With an accuracy percentage of 98.8%, the suggested strategy impressively outperformed existing tried-and-true methods. These findings have important ramifications. They highlight the potential for computer intelligence to transform healthcare, as well as the importance of early detection in improving patient outcomes. We can create a future where lung cancer is easier to treat and survive by adopting cutting-edge technology and treatment approaches, which will eventually improve the quality of life for those who are impacted. Stated differently lung cancer is the most important global cause of death for both men and women. Other studies show that lung cancer in the United States in 2015 accounted for around 13% of all cancer diagnoses. The American Cancer Society estimates lung canceris responsible for 27% of all cancer-related fatalities. Therefore, it's important to thoroughly evaluate and monitor lung nodules in their early phases of growth. Using the ML and DL approaches for forecasting cancer growth and progression, the researchers in this study examined the onset and course of cancer. These labels are used to additional picture analysis, which is usually shown as a histogram. The versatility and ease of use of the LBP texture operator have led to its widespread adoption in many applications.

REPORTING LUNG CANCER USING DEEP LEARNING FRAMEWORK

Racista Khalid et al. It has been suggested in this system that lung carcinoma, often known as lung cancer, is a serious global hazard because of its aggressive nature. Treatment effectiveness depends on early intervention since the illness is caused by unchecked cell growth in lung tissues. Since treatment efficacy decreases as the illness advances, early identification is critical. Although blood tests could reveal abnormalities after a few years, Computed Tomography (CT) scanning is still the principal technique for detecting lung cancer in its early stages. In order to identify tumor forms, medical personnel can classify pictures as either normal or abnormal, and CT scans are essential to this procedure. Automating the identification of lung cancer may be achieved by the use of prepared models such as the folding network (CNNS), especially Lent, Alex Net, and VGG-16, were trained on data records such as Imagentet. The famous CNN model Alex Net architecture is used in this study's suggested model to analyze CT scans and look for indications of lung cancer. A Softmax classifier receives features taken from the Alex Net model's last fully connected layer in order to perform classification. The accuracy rating of 99.52% achieved by combining Alex Net with the Softmax layer is remarkable. Cancer is a condition brought on by the body's tissues and cells growing abnormally. Cancer has long been considered one of the worst illnesses endangering human life. According to the estimates, 1.8 million new cancer cases examine more than 606,520 deaths in the United States in 2020 and 247,270 new cases of lung cancer. After the 2018 analysis,18.1 million new illness cases will be added to the world's database of malignancy cases, and about9.6 million of those instances would result in death. With a growth rate of 13% Lung cancer is the most well-known type of disease in the world. In a clinical setting, evaluation and interpretation of lung scans is a delicate process that requires patience and high level of skill.

CLASSIFICATION AND PREDICTION OF LUNG CANCER USING IMAGE PROCESSING AND MACHINE LEARNING

In this method, Yacine Khalid et al. have presented Lung cancer continues to be a strong foe in the field of medicine, posing serious difficulties for physicians everywhere. The underlying cause of cancer and a conclusive treatment are still unknown, despite continued scientific efforts. On the other hand, there is optimism because early cancer identification and therapy can greatly enhance patient outcomes. Medical professionals use a variety of image processing techniques to analyze medical pictures, including Computed tomography (CT) scans for early stages to diagnose disease. To recognize areas of care within the lungs, these approaches may generally link to distinctive extractions, noise reduction, problematic areas identification, and patient health insurance. By demonstrating machine learning and image processing technology can effectively diagnose and forecast lung cancer, this work advances the field. In order to commence the study, data record consisting of 83 ct images from 70 different individuals was assembled. Image pre- processing methods, such as the use of a geometric mean filter, were applied Improved photo quality and provide the best possible input for further analysis. After pre-processing, the K-means approach for picture segmentation made it easier to identify

pertinent areas in the photos. The segmented photos were then classified using a variety From machine learning technologies such as Random Forests (RF), K-Nearest Neighbors (KNN), and Artificial Neural Networks (ANN). The experimental results showed that the ANN model was better blocked alternative categorization strategies and showed increased accuracy in predicting lung cancer. Every year, lung cancer, one of the deadliest forms of the illness, claims the lives of almost one million individuals. Identification of lung nodules on chest CT images is vital given the present status of medical research and practice. This is because lung nodules are become more and more common. This directly means that CAD technology must be used to achieve early lung cancer detection goals.Advanced X-ray technology is used during a CT scan to take pictures of the human body from several perspectives. After that, the pictures are entered into a computer, which uses its processing power to create cross-sectional images of the internal organs and tissues of the body.Two distinct studies were conducted to teach and evaluate a CAD technique. In one study, computer-generated ground truth was employed in a computer simulation.

ALGORITHMS FOR MACHINE LEARNING FOR THE PREDICTION OF LUNG CANCER INCIDENCE RATES

Dembrito, Abderraouf et al. has suggested in this scheme, Cancer is becoming more and more common, which poses a serious threat to global healthcare systems. It gets more and harder for human specialists to anticipate cancer incidence and mortality rates since there are so many different varieties of the disease and there aren't enough trustworthy statistics on them. Machine learning algorithms have become extremely effective instruments for accurately and minimally erroneously predicting unknown data in response to this problem. In order to estimate lung cancer incidence rates across 10 European nations, the authors of this research investigate Using Support Vector Regression (SVR), Long Short Terminology Memory (LSTM) Network, and Backpropagation Learning Algorithm (often connected with Artificial Neural Networks). The dataset offers a thorough historical view, spanning from 1970 onward. The study's findings show that machine learning algorithms may it can be used to predict the incidence of lung cancer with high levels of accuracy.But when compared to the other algorithms under consideration, Support Vector Regression proves to be the most successful in providing better prediction performance out of all of them. The abnormal cell division of any tissue or organ is the source of the cancer, which is known as a malignant tumor. When there is no chance of recovery, there is severe suffering or perhaps death. Cancer instances have been seen historically and will likely continue to be observed in the future. Experiments and investigations have been conducted to aid early diagnosis and treatment of cancer disorders. Even though cancer diagnoses can now be identified more promptly because to technological advancements, the disease can still be fatal in situations where it spreads swiftly or to other areas.

III. EXISTING SYSTEM

Medical professionals are largely responsible for X- ray picture analysis. Regardless of cost, patients want accurate interpretations of these photos. Chest radiography provides a number of benefits, but mistake resulting from MRI interpretation has long been a big problem for doctors and radiologists. As per Early cancer diagnosis and treatmentrelated deaths globally. The primary issues are inadequate screening tools and delayed diagnosis. Radiologists can properly predict the lung nodule's malignancy risk with the use of this approach. The purpose of this work is to use deep learning to identify and categorize lung cancer. We employed the Faster Regions with CNN (Fast R-CNN) in conjunction with the Convolutional Neural Network (CNN) method. When compared to the results of the literature, our model yields highly positive results and offers a medical aid model with a high accuracy rate.

IV. PROPOSED SYSTEM

The goal of the suggested system is to use Artificial Neural Network (ANN) techniques to create a sophisticated model for predicting lung cancer images. In order to do this, we will make use of a meticulously selected collection of lung cancer photos, making sure that each image is accurately labelled with the presence or absence of lung cancer.Standardizing picture sizes, normalizing pixel values, and maybe enriching the dataset to improve model generalization are all part of the data pre- processing step. The main component of the system is an artificial neural network (ANN) architecture that includes fully connected layers for classification and convolutional layers for efficient feature extraction from the pictures. A split dataset will be used for training, and the model will be continuously validated to adjust hyper parameters and prevent overfitting. Evaluation criteria that will be used to evaluate the power of a model to another modeltest set include accuracy, precision, recall, and F1 score.

V. MODULE DESCRIPTION

INPUT LUNG CT IMAGE

Lung-CT images with little noise compared to scanned and MRI images. This allows you to absorb CT images and recognize your lungs. The main advantages of the lungs. The main advantages of computed tomographic images with clarity, low noise and distortion. The average and variance can be easily calculated. The calculated value is very close to the original value.

Fig.3.The Lung CT Image

PREPROCESSING

In order to effectively analyze the medical imaging data, the preprocessing module is essential. Several methods are used at this stage to clean and standardize the incoming data. This entails adjusting the pixel intensities to guarantee uniformity, scaling the photos to a consistent resolution, and removing any possible noise or artifacts that might skew the results of later investigations. The objective is to provide a high-quality, standardized dataset that will enable the best possible learning experience in the latter phases of the lung cancer detection process.

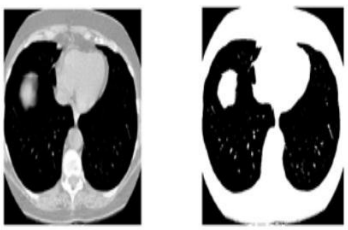

Fig .4. Preprocessing

VI. CONCLUSION

To sum up, the creation of an Artificial Neural Network (ANN) for lung cancer early detection and prediction marks a substantial breakthrough in the application of machine learning to better healthcare outcomes. Through the use of extensive medical imaging data and strict training and assessment procedures, the suggested approach seeks to improve the diagnostic capacities that are essential for addressing the worldwide lung cancer epidemic. Early detection techniques might be completely changed if the system is successfully integrated into clinical practice while taking interpretability, scalability, and user-friendliness into account. This creative method not only emphasizes how crucial it is to incorporate state-of-the-art technology into healthcare, but it also shows how promising Artificial Neural Networks can be in facilitating quicker and more efficient interventions, Ultimately, this improves results regarding patient care and lung cancer diagnosis.

Abstract- Over time, Artificial Intelligence (AI) has profoundly influenced consumer engagement with clothing and accessories within the broader domains of fashion and e-commerce. Consequently, this study seeks to investigate the viabilityof such AI-based technologies as computer vision and deep learning, augmented reality(AR), in providing a more user-friendly exciting online shopping experience via virtual try-ons and AI-enhanced virtual wardrobes. As online shopping continues to grow, customers mainly experience difficulties with size selection, fit, and style, all without the ability to physically try on items. Virtual try-on technology uses AI and mobile camera data to create realistic images of apparel on a person's body, thus trying to boost confidence in buying decisions and, consequently, lower return rates. The AI-based virtual wardrobe and recommendation systems scan the users' preferences, past purchases, and present body measurements using machine-learning algorithms to suggest outfits to the users.

The present study will enable us to gain insights into the key methods driving the development of such innovations, including deep learning architectures for body segmentation, computer vision techniques used in real-time garment fitting, and recommendations related to personalization and user interest.

Data privacy concerns, computational needs, and a host of other concerns based on the limitations of current AI models in accurately portraying the actions and movement of fabrics will also be addressed. This study, by way of a comprehensive review of current solutions and future trends, demonstrates how AI-based technologies in fashion are

closing the gap between online and offline shopping experiences. This finding indicates that the marriage of AI and online fashion retailing has a high degree of

potential to improve user satisfaction and sales, and to drive sustainability through a lower rate of returns and a lower rate of overproduction. The value addition through AI in terms of acceptance and integration into the fashion sector is likely to grow as development progresses.

Keywords: AI and Fashion, virtual try-on, virtual closet, augmented reality, e-commerce, computer vision, deep learning, recommendation.

I. INTRODUCTION

The fast-paced development of Artificial Intelligence (AI) has impacted various industries of commerce, varying from the clothing and e-commerce sectors. With the trend of online shopping continuing, customers are finding it difficult to choose ensembles not only that would be a good fit but also suit their taste, body type, and style. In contrast to traditional physical retailing stores, where customers are able to try dresses before buying an item, most online shops do not provide that benefit, resulting in indecisive buying, increased return orders, and unhappy customers. AI-driven innovations, mostly virtual try-ons and digital closets, attempt to fill the gap by seeking to provide the customer with an improved, customized interactive buying experience.

Virtual try-on technology allows for real-time simulation of an individual wearing clothing by a combination of computer vision, deep learning, and augmented reality (AR). By using an AI-based mobile camera, it can scan body proportions, posture, and even skin tone in order to suggest clothing that would flatter the user. This addressed a better shopping experience plus the reduction of returns due to poor fit or dissatisfaction with how an outfit looks when worn. Secondly, an AI-based virtual wardrobe optimizes personalization by ensemble recommendations through the current wardrobe collection, buying history, and an entire combination of the user's style. Such systems use machine learning algorithms to match trends and create ensembles that fit individual designs' sense of style and latest seasonal trends.

One of the major developments in fashion technology using AI is the addition of AI features to identify one's skin tone in an effort to offer appropriate colors and patterns to make them look more beautiful. Conventional styling was entirely dependent on personal visits to a styling consultant, who would suggest shades and patterns for the skin undertones.To this point, this entire process can be automated with remarkable accuracy. This would be done with image recognition and deep learning through which skin tones are classified, matching it with color palettes to help consumers in making informed decisions about their fashion. It enhances personalization and brings diversity and inclusion into the fashion by catering for aesthetic tastes alongside the ambit of cultural styles.

For one, the use of AI in fashion creates the necessary foundation for far-reaching sustainable actions within the industry and beyond. The online shopping avenue has resumed a kind of return in a large return system, which makes it a waste pile on both the logistics and nondelivered inventory fronts. Virtual fitting of garments is designed to help consumers make smarter choices leading to fewer returns while virtual wardrobes encourage customers to get the most out of their wardrobes instead of aiming for purchasing new clothing all the time. Moreover, with AI, fashion brands can better forecast demand, thereby easing the pressure on overproduction and reducing their negative impact also on the environment.

The manuscript elucidates the technological underpinnings that support virtual try-on and virtual wardrobe services, addresses challenges associated with AI personalization, and examines ethical considerations including data privacy and biases inherent in fashion recommendations. The objective of this research is to demonstrate that AI can facilitate personalized, efficient, and sustainable shopping experiences for consumers, contingent upon a thorough analysis of current trends and future opportunities.

II. RELATED WORKS

Ying Huang a, Tao Huang [1] This paper proposes an outfit recommendation system based on deep learning. The system not only evaluates whether an outfit is beautiful or not but also recommends suitable outfits to users from a given list of clothing. The model presented in this paper consists of two components: a feature extractor based on ResNet-50 and a binary classifier determining the quality of an outfit as good or bad. Since it is a deep learning-based model, the model requires a large dataset for training. A dataset consisting of 409,776 outfits and 644,192 clothes was downloaded from the fashion site Polyvore.com. Based on the dataset, the model was trained, and the accuracy of the performance was more than 84%. Apart from that, the system is also capable of recommending daily outfits to users.

CSANÁK [2] The research is about the role of Artificial Intelligence (AI) in the fashion industry and how it is transforming various aspects, including design, production, marketing, sales, and consumer experiences. It examines how AI-driven technologies, such as big data analysis, virtual fitting applications, and predictive algorithms, are influencing fashion trends and industry processes.The study also highlights ethical and sustainability concerns, questioning whether AI-driven automation and digitalization might disrupt the artistic and cultural value of fashion. Additionally, it explores AI's capability to function as a fashion designer, analyzing whether AI can replace human creativity in design.

Here is a brief overview of each paper and the technology used:

Jammalamadaka et al. (2013) - Parsing Clothes in Unrestricted Images (BMVC) [3]. The paper presents a clothing parsing method in unrestricted images, i.e., with different poses and occlusions. The authors propose an approach using conditional random fields (CRFs) and machine learning techniques to parse clothing objects from images in an efficient manner. The work is significant for applications like virtual try-on, fashion recommendation, and online shopping automation.

Liu et al. (2012)[4].The paper presents a fashion retrieval system that aligns clothing objects in street images with online shop catalog images. The authors use part-based alignment techniques and deep learning-based feature extraction to improve retrieval performance. The method helps users find similar clothing objects online by analyzing images captured in real-world environments.

Wang & Ai[5] The paper addresses clothing segmentation in overlapping and crowded scenarios, where more than one person is present in the same image. The authors' model uses graphical models and machine learning techniques to detect and segment clothing regions accurately. The work is useful for fashion analysis, surveillance, and social media.

Liu et al. (2012)[6]. The paper introduces an AI-powered fashion recommendation system called "Magic Closet," which suggests outfits based on user preference and fashion trends. The system applies deep learning, visual recognition, and rule-based reasoning to analyze clothing styles and offer personalized fashion advice.

He et al. (2016)[7] A deep learning architecture that significantly improves image recognition tasks using residual learning architectures. ResNet enables deep neural networks to learn efficiently by preventing the vanishing gradient problem and therefore is a cornerstone in computer vision, including fashion image analysis.

6.Abadi et al. (2016)[8]This paper introduces TensorFlow, an open-source machine learning system developed by Google for large-scale deep learning applications. TensorFlow supports distributed computation, making it highly scalable for image classification, object detection, and natural language processing tasks. It is a key contributor to training deep learning models used in fashion image recognition.

7. Jia et al. (2014)[9] This paper introduces Caffe, an open-source deep learning system optimized for speed and efficiency. Caffe is a widely used choice in image processing and computer vision applications, including fashion analysis. It provides pre-trained models and feature extraction tools, making it a researcher and developer favorite among the AI and fashion communities.

8. Liu Z, Luo P, Qiu S, et al. (2016) [10] DeepFashion article discusses DeepFashion, a large scale dataset with sophisticated annotations for clothes recognition and retrieval. It establishes several benchmarks in the areas of clothing attributes prediction, retrieval of clothes, and fashion landmark detection. Deep learning based techniques help in creating a robust dataset capable of accurate recognition and retrieval of fashion images to meet high standards in the application of computer vision for fashion.

9.. Hu Y, Yi X, Davis L S. (2015) [11] Collaborative Fashion Recommendation This paper proposes a collaborative recommendation model based on functional tensor factorization that recommends fashion items to users based on preference. The model improves the existing fashion recommendation systems by including multimodal data such as user-item interactions as well as visual modality features within its scope and thus raises the bar from simple fashion suggestions to personalizing more closely relevant recommendations.

10.. Jagadeesh V, Piramuthu R, Bhardwaj A, et al. (2014) [12] Visual Recommendations from Street Fashion This paper conducts a study whereby it uses a large number of images that are from street fashion to take fashion recommendations to the next level. It introduces a form of framework, which uses visual cues extracted from one's fashion images incorporated with machine learning techniques to provide recommendations based on trendy items. The approach gathers huge amounts of data trying to catch what is really important in terms of fashion preferences and coming up with relevant suggestions.

11.. Yamaguchi K, Berg T L, Ortiz L E. (2014) [13] This paper is about the Visual Popularity in Online Fashion Networks study describing fashion trends and the propagation of popularity of fashion items via online fashion communities. By utilizing image processing and social network analysis, it further explores how the popularization of fashion items takes place and to what extent visual features contribute to their successful spread. This research tends to shed light on the social and aesthetic factors that influence fashion trends.

12. Huang J, Feris R S, Chen Q, et al. (2015) [14] A Cross-Domain Image Retrieval proposes the dual attribute-aware ranking network which makes the retrieval performance state of the art for cross-domain image retrieval. With attribute-aware embeddings, the model achieves improved retrieval accuracy for fashion applications. It allows visually similar clothing items to be found by users through entire domain differences, e.g., studio images as opposed to real-world street fashion images.

13. Chen H, Gallagher A, Girod B. (2012) [15] A paper Describing Clothing by Semantic Attributes proposes a system describing clothing images using semantic attributes such as color, pattern, and style. It makes use of machine learning techniques at its core to bring forth detailed descriptions about clothing items with the aim of rendering such items searchable and retrievable in fashion applications. The research also helps to improve the quality of fashion recommendations and e-commercialization by providing meaningful descriptions of clothing items.

III. EXISTING SYSTEM

The growing demand of e-commerce impacts the development of numerous technologies aimed at improving online shopping. Conventional online fashion retail continues to rely upon static images, sizing charts, and customer reviews to aid the customer with the decision-making process. Often these means prove ineffective to provide a judgment on how a product would appear and the fit it would provide an individual. Thus, high rates of product returns, customer dissatisfaction, and uncertainty regarding sizing continue to prevail.

In an attempt to face this challenge, many AI-driven solutions have arisen in online fashion retail sectors; these include recommendation systems, virtual try-ons, and digital wardrobes.The systems in use incorporate completion methods through artificial intelligence technologies, that is, computer vision, deep learning, and augmented reality (AR), for improved user experience.

AI-Based Recommendation Systems

Recommendation systems in online fashion retail use artificial intelligence to allocate apparel items according to user interests, purchase history, and web history. Collaborative filtering and content-based filtering approaches are then used in systems to analyze user behavior and recommend personalized clothing combinations. Some also took inputs from demographics and other user feedbacks to improve the recommendations further. One weakness of such systems is their focus on the selection of clothing; any visualization of the clothing itself on the body of the customer is not their concern. Ultimately, they do not, therefore, offer an isolated advantage to this notion.

Virtual Try-On Technology

Virtual try-on solutions use augmented reality and computer vision to overlay digital garments onto a user's live image or pre-uploaded photo. Many e-commerce brands and fashion retailers have integrated virtual try-on features into their apps and websites, allowing customers to visualize how different outfits would look before making a purchase.

There are two main types of virtual try-on systems:

2D-Based Try-Ons: These systems superimpose flat images of clothing onto the user's image, offering a basic visual representation. While they provide a quick preview, they lack depth and realistic fitting accuracy.

3D-based try-ons: The latest solutions rely on a 3D model coupled with AI-based segmentation of body parts to produce real draping, motion, and fit for the garments. These applications capture scans of the user's body where the application ensures nothing but the very best in terms of fitting. However, its accuracy can still be affected by several factors, including the simulation of fabrics, light problems, and some mayhem with body posture.

Some of the existing platforms, such as Snapchat's AR lenses and shopping apps like Nike Fit, use AI-driven scanning to enhance virtual try-on experiences

However, while this technology has advanced a lot, the underlying technology is still in the process of evolving and, as such, virtual fitting is not yet flawless.

AI Provides Wardrobe Virtualization

Virtual wardrobes are newly popular due to the recommendations made by AI for users to organize their wardrobes along with combinations in relation to outfit pattern building. Some existing virtual wardrobe systems assist users with choosing a collection of clothes they already own, matching outfits according to color combinations, considering climatic conditions, and preference in personal style.

Such applications, like Cladwell and Smart Closet, enable users to digitally organize their wardrobe in which images of clothing are uploaded. AI algorithms then suggest mix-and-match outfit combinations that help users partially realize their full potential with what they have in their wardrobe. However, most of these applications demand laborious manual data entry in which users upload images and classify clothing in clothes into subcategories. This process could be automated if image recognition with AI can be integrated with camera scanning on mobile.

Shortcomings of the Existing System

Despite the increasing prominence of recent technologies in fashion that incorporate artificial intelligence, significant shortcomings persist:

Accuracy and Reality: Virtual try-on technologies have a tendency to produce deceptive simulations about the motion of some fabrics, their texture, and the interaction of light.

Size Considerations: Size suggestions typically are based on the assumed size chart which does not reflect the variation in single body measures.

User Interaction: User input in virtual closet software is typically needed manually and hence leaves minimal space for user interaction and participation. Invasion of Privacy: The gathering of user images and personal information also outbursts in terms of privacy, safety, and security issues, making data protection a major issue..

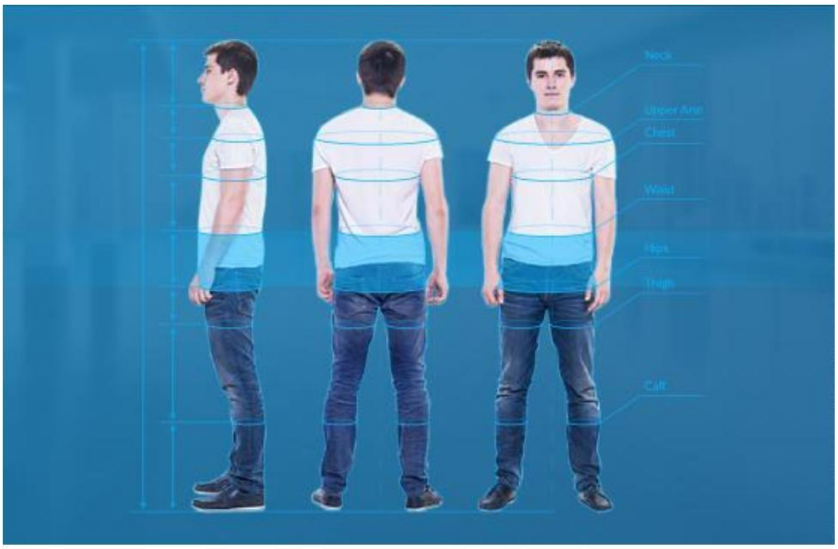
IV. OUR SOLUTION

It is based on artificial intelligence to revolutionize online shopping by using a Virtual Try-On System coupled with an AI-Augmented Virtual Wardrobe. It uses computer vision, deep learning, and augmented reality (AR) technologies to give a real simulation of garments on the users' bodies along with personalized suggestions.Our process attempts to bridge the gap between brick and mortar stores and internet shopping by enabling users to visualize how clothing will look on their body shape, skin tone, and style preference.

Personalized Color Guidance and Skin Tone

Artificial intelligence in fashion technology can take a different innovative path by applying computer vision and machine learning to scan a person's skin color. Using web facial recognition and color detection algorithms will recommend the colors of clothing that would best suit the user when shopping. This will be very useful for students making online purchases since color variations are somewhat difficult to ascertain without trying them on first, thus AI-powered color matching is bound to improve customer satisfaction and confidence when making purchases.

Virtual Try-On System



Virtual Try-On System is an AI technology that is based on deep learning and computer vision and enables one to envision how a particular outfit will fit the individual's body in real-time with consideration for the person's body shape.The following areas are covered by the technology:

Body Segmentation and Pose Estimation: Deep learning algorithms conduct body shape detection, pose detection, and proportion detection based on their input from a video stream from a mobile phone camera. This way, the system can superimpose clothing on the subject with near-photorealistic resemblance.

Fabric Simulation and Fit Estimation: High-level AI models second guess the way the fabric drape on and move around the user's body by estimating cloth properties, doing their best to keep the state of the fitting in its closest proximity to an actual fitting as possible.

Augmented reality (AR): Further improvement on such comes in the form of augmented reality, which renders a multi-dimensional aspect of oneself in real-time, from every possible angle while trying on different attires.

With the aforementioned features, users can now be able to make informed buying decisions, consequently lowering the return rates and improving customer satisfaction.

AI-Powered Virtual Wardrobe

A virtual dressing system will work based on machine-learning algorithms employed to generate outfit recommendations scattered over the user, past purchases, and contextual variables like season, events, and individual style. The key pieces are:

Personalized Dressing Suggestions-AI would recommend outfits that are most suitable for their personal style and interests based on user-uploaded images and purchase history.

Skin Tone Matching-The system, through a deep learning-based technique, detects skin tones and suggests outfits that enhance user complexion. The chosen colors for the clothing make appearances even more personalized.

Suggestions Based on Weather and Events-The system would cherry-pick standard clothing depending on such external elements as the current weather and social events thus, providing a seamless shopping experience.

Artificial Intelligence-Driven Trend and Style Predictions

However, to personalize even further, the system would implement AI-driven trend analysis of fashion by:

Keeping track of what's trending on social media, fashion blogs, and business reports to suggest fashionable outfits. Modifying dress guidance over time, based on user preference.

Offering styling tips from body proportions so that the users could find better fits.

Ethical Considerations and User Privacy

As the fashion recommendations made by AI involve personal information, our approach to compliance with the public good and ethical AI use is as follows:

Apply on-device processing wherever possible to minimize the transmission of data for that very purpose.

Employ transparent AI models to prevent skin tone or body shape biases.

Allow users control over data by letting them opt in or out of personalized features.

V. FUTURE WORK

With the technology of artificial intelligence blossoming, soon enough AI-driven fashion recommendations and virtual try-ons would be more sophisticated and personalized than ever. There is a range of future testing that can help

improve the combined effectiveness of AI-driven fashion technologies and the experience of the users, according to this research.

The Simulation of Fabric Behavior and Virtual Try-Ons

Existing virtual try-on technology, until now, hasn't transcended to actually draping the clothing on the contours of the body, able to recreate the fabric in question with regard to properties such as stretch, flow, or drape across the body. Future innovations may utilize artificial intelligence models trained on expansive data regarding fabric characteristics to enrich the realistic illustrations of texture, motion, and properties of elasticity. Such innovations will bring more realism and immersion to the user's online shopping experience.

AI-Powered Fashion Assistants for Outfit Planning

Coming soon to an exciting life is the virtual closet wherein clothing assistance gives real-time styling suggestions based on the hottest clothing trends, specific weather detail, or an event of renowned charm. By assessing the user's closet, shopping history, and social calendar, the AI assistant suggests outfit choices for events. Hence, this makes sure that one can always make the best use of his or her wardrobe. One can further enhance the exciting shopping experience of interactive shopping by offering styling advice with the aid of voice assistants or chatbots.

New: Augmented Reality will Make the Experience Even Better

One of the issues to be studied in future work is the coming together of artificial intelligence and augmented reality so that users could at that time "try on" different clothing in real-time through the camera of the smartphone. That will create an even better shopping experience since the buyer will visualise how the clothes will look on them in different surroundings, under different lightings with different angles. The technology screams for enhanced AR rendering and AI-driven pose estimation, making it so accurate that the virtual try-on will be very close to a real-person try-on.

Ethical AI and Bias Reduction in Fashion Recommendations

A very big area of research for the next deployment is the aspect of confronting bias within AI to determine fashion recommendations. Fashion recommendations based on AI may be inherently biased due to biases in the datasets used to train the model. Future work must focus on the creation of a training dataset that is diverse and representative-a critical initiative for attaining inclusive and accessible fashion recommendations via AI. Attention would need to be focused on transparency in the AI decision-making process, allowing users some insight into the manner in which recommendations are generated.

Sustainable Fashion and AI-Powered Sustainable Recommendations

AI could foster sustainability within the fashion business by pairing outfits ...from whatever exists in the closet, thereby supporting reuse while minimizing unreasonable shopping. AI-driven sustainable shopping assistants could also develop in the near future, in which a consumer shall be prompted to opt for clothes that are as eco-friendly as possible, from responsible-branded companies with lower environmental footprints. With the support structures of sustainability inputs by AI, the conscious consumer thus can make a decision informed in the fashion world.

Cross-Brand and Multi-Platform Integrated Virtual Wardrobe Most virtual wardrobe applications today are based on a single brand platform. The building of a universal virtual closet that is responsive to multiple fashion brands for simple mix-and-match operations could change with subsequent innovations. This will be supportive of a tolerant strategy and harmonized experience, thus making online fashion purchasing dynamism very active and interconnected.

VI. CONCLUSION

The addition of Artificial Intelligence (AI) to the fashion industry has significantly enhanced the online shopping experience by being more interactive, customized, and efficient. Virtual fitting system and AI-powered wardrobes are changing the way customers select and purchase clothes by using advanced technologies such as computer vision, deep learning, and augmented reality(AR).These technologies allow the customers to see how the clothes fit on their bodies before purchasing it, reducing the return rate and improving the customer experience.

In spite of several advantages, issues in integration of AI in the fashion world persist. Some of the issues include computational efficiency, realistic simulations of fabrics, and ethical considerations for data privacy. It is also important to minimize biases in AI models so that recommendations to users of different body shapes and skin tones are inclusive and unbiased. With the development of AI technology, machine learning and augmented reality will keep enhancing virtual try-on systems, hence making them more realistic and available in the international market.

In the future, AI can revolutionize not only e-commerce but also sustainability in the fashion sector. By reducing product returns and overstocking, AI-driven product recommendations can drive brands towards more sustainable practices. With future progress in research and innovation in this field, AI-based virtual wardrobes and virtual try-ons will be among the major drivers in shaping the future of digital fashion, giving consumers a more immersive, efficient, and personalized shopping experience.

VII. ACKNOWLEDGMENT

First of all, I would like to express my gratitude and appreciation to all the individuals who have facilitated my progress towards achieving this point in my research on artificial intelligence integration in fashion and e-commerce. I also appreciate the researchers who have discovered artificial intelligence, computer vision, and augmented reality, and without whose groundbreaking efforts, virtual fitting solutions and wardrobe management systems have not been feasible. This has provided a sound foundation for an unsettling AI that improves online shopping by providing garments and virtual fittings of these garments frequently in real time.

These projects and efforts were made possible with knowledge and guidance from the wonderful researchers, developers, and experts in the field.Efforts in deep learning, skin tone analysis, and fabric recognition help clarify how AI systems can not only inform individual consumers about well-tailored outfits but also suggest colors and styles that suit a person's complexion. AI's capability for skin tone recognition and fashion recommendations is an important step toward inclusive and personalized shopping experiences.

Another group of acknowledgement goes to those involved in the practical development and implementation of AI-powered fashion technologies, including engineers, designers, and user experience specialists, whose efforts in bridging the gap between technology and consumer needs exemplified the extent to which AI can revolutionize the fashion industry.

Finally, I'm thankful for my mentors, colleagues, and peers who provided feedback, encouragement, and really constructive exchanges through this research process. Their contribution to what narrowing down the study means for AI-enhanced fashion technology has served to greatly refine ideas toward a meaningful contribution within the field.

The final address for me is in dedication to the ongoing vision of fashion and technology that AI, as a power, through user empowerment continues creating for more personalized, efficient, and enjoyable shopping experiences.

VIII. CONCLUSION

The addition of Artificial Intelligence (AI) to the fashion industry has significantly enhanced the online shopping experience by being more interactive, customized, and efficient. Virtual fitting system and AI-powered wardrobes are changing the way customers select and purchase clothes by using advanced technologies such as computer vision, deep learning, and augmented reality(AR).These technologies allow the customers to see how the clothes fit on their bodies before purchasing it, reducing the return rate and improving the customer experience.

In spite of several advantages, issues in integration of AI in the fashion world persist. Some of the issues include computational efficiency, realistic simulations of fabrics, and ethical considerations for data privacy. It is also important to minimize biases in AI models so that recommendations to users of different body shapes and skin tones are inclusive and unbiased. With the development of AI technology, machine learning and augmented reality will keep enhancing virtual try-on systems, hence making them more realistic and available in the international market.

In the future, AI can revolutionize not only e-commerce but also sustainability in the fashion sector. By reducing product returns and overstocking, AI-driven product recommendations can drive brands towards more sustainable practices. With future progress in research and innovation in this field, AI-based virtual wardrobes and virtual try-ons will be among the major drivers in shaping the future of digital fashion, giving consumers a more immersive, efficient, and personalized shopping experience.

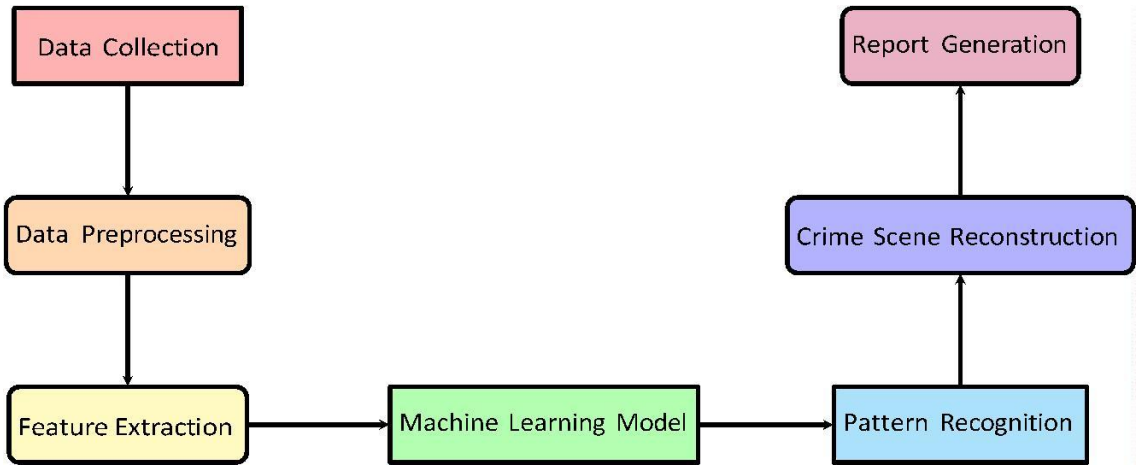
ABSTRACT:

The incorporation of AI and ML into forensic science is a major step forward in analyzing crime scenes, providing fresh approaches to reconstructing crime scenes. This study investigates how AI-powered forensic analysis can improve the precision and effectiveness of reconstructing crime scenes. Forensic professionals can use ML algorithms to analyze intricate datasets, such as biometric information, environmental factors, and physical proof, in order to create in-depth crime scene reconstructions. The article explores different machine learning methods like computer vision, natural language processing, and data mining, emphasizing their importance in enhancing evidence interpretation and pattern recognition. Furthermore, we discuss the difficulties and moral factors related to integrating AI in forensic situations, such as privacy concerns with data and biases in algorithms. Case studies illustrate how AI can be used in real-life crime scene investigations, highlighting the transformative impact of these technologies on forensic science. The results indicate that utilizing AI in forensic analysis improves both the precision of reconstructing crime scenes and the speed of investigations, leading to better outcomes in law enforcement and justice.

KEYWORD: AI, ML, Forensic Science, Crime Scene Reconstruction, Computer Vision, NLP, Data Mining, Evidence Interpretation, Pattern Recognition, Algorithmic Bias, Data Privacy, Investigative Processes, Law Enforcement, Forensic Technology, Biometric Analysis are all related topics in the field.



INTRODUCTION:

In the changing field of forensic science, the blending of artificial intelligence (AI) and machine learning (ML) is revolutionizing conventional approaches to analyzing and reconstructing crime scenes. The demand for more accurate, effective, and all-encompassing methods of crime scene analysis is becoming more evident with the rise of more intricate and widespread criminal behaviors. AI-powered forensic analysis shows great potential in overcoming these challenges by improving the skills of forensic professionals and law enforcement organizations. The reconstruction of a crime scene is an essential part of forensic science, with the goal of reconstructing the sequence of events before, during, and after the crime. Historically, this procedure has depended greatly on manual examination and expert understanding, which may consume a lot of time and be vulnerable to human mistakes. AI and ML bring about a new way of doing things by presenting automated systems that can handle vast amounts of data with incredible speed and precision. These technologies allow for the examination of a variety of data formats such as visual, auditory, and textual information, leading to a more complete comprehension of crime scenes.

Machine learning applications like computer vision and natural language processing enable the identification and understanding of important evidence components, like fingerprints, facial recognition, and voice analysis. Additionally, data mining tools have the ability to discover patterns and connections that may be missed by human investigators, providing fresh perspectives on criminal actions

and intentions. Even though AI-driven forensic analysis offers clear benefits, there are multiple obstacles to its implementation. Proper management of ethical concerns, like safeguarding data privacy and addressing algorithmic bias, is essential for ensuring the effectiveness and fairness of AI applications. Moreover, the dependability of AI systems in legal settings is crucial, requiring thorough validation and openness. This document investigates the merging of AI and ML in forensic analysis, with a specific emphasis on how they improve crime scene reconstruction. Through the analysis of existing techniques, real-life examples, and upcoming trends, we hope to underscore the significant impact these technologies can have on forensic science, specifically in improving the precision and effectiveness of investigative procedures.

AI-Driven Forensic Analysis Process Flowchart

Literature Survey

The integration of artificial intelligence and machine learning in forensic science has garnered significant attention in recent years. Researchers are exploring how these technologies can enhance crime scene analysis, evidence interpretation, and investigative processes.

1. AI and Computer Vision in Forensics

Recent studies have demonstrated the effectiveness of computer vision in analyzing visual data from crime scenes. A study by Chen et al. (2022) explores the application of deep learning algorithms to automate the analysis of crime scene photographs, enabling the identification and classification of key evidence such as weapons, clothing, and other objects. Their approach significantly reduces the time required for manual examination, improving both efficiency and accuracy (Chen et al., 2022).

2. Natural Language Processing for Evidence Analysis

Natural language processing (NLP) has shown promise in analyzing textual data from witness statements and police reports. In a study by Kumar and Patel (2023), NLP techniques were used to extract relevant information from large volumes of unstructured text, allowing investigators to identify patterns and discrepancies in witness accounts. This approach helps in constructing a more coherent narrative of events, supporting more effective case management (Kumar & Patel, 2023).

3. Data Mining and Pattern Recognition

The use of data mining techniques to uncover patterns and correlations in forensic data is another area of active research. A paper by Johnson et al. (2023) highlights the application of machine learning algorithms to analyze biometric data, such as fingerprints and DNA profiles. Their study demonstrated the potential of these techniques to link seemingly unrelated cases and identify repeat offenders, thereby aiding in criminal investigations (Johnson et al., 2023).

4.Ethical Considerations and Algorithmic Bias

While AI offers significant benefits, ethical concerns remain a critical consideration. A comprehensive review by Smith and Rodriguez (2022) examines the challenges associated with algorithmic bias and data

privacy in forensic applications. They emphasize the need for transparent and accountable AI systems to ensure fair outcomes in legal contexts (Smith & Rodriguez, 2022).

5. Case Studies and Practical Applications

Several case studies illustrate the practical applications of AI in real-world forensic investigations. For example, a case study by Lee et al. (2024) describes how AI-driven analysis was used to reconstruct a complex crime scene involving multiple suspects. The study highlights the role of AI in processing diverse data sources, including video footage and environmental sensors, to provide a comprehensive understanding of the crime scene (Lee et al., 2024).

6. Future Directions in AI-Driven Forensic Analysis

Emerging research is exploring new directions for AI in forensics. A recent paper by Thompson et al. (2024) investigates the potential of using AI for predictive policing and crime prevention. By analyzing historical crime data, AI systems can identify high-risk areas and suggest proactive measures for law enforcement agencies (Thompson et al., 2024).

This literature survey underscores the transformative potential of AI and ML in forensic science. As these technologies continue to evolve, they promise to enhance the accuracy, efficiency, and scope of crime scene reconstruction, ultimately contributing to more effective law enforcement and justice outcomes.

PROPOSED METHODOLOGY:

The AI-driven forensic analysis process involves a series of interconnected steps designed to enhance crime scene reconstruction through the application of machine learning techniques. This section describes each step in detail, highlighting the technologies used and the mathematical principles underpinning them.

1. Data Collection

The first step involves collecting data from various sources associated with the crime scene. This includes:
Images and Videos: Captured from surveillance cameras, smartphones, and other recording devices.

- Textual Data: Witness statements, police reports, and other documents.
- Biometric Data: Fingerprints, DNA profiles, and facial recognition data.
- Sensor Data: Environmental readings from IoT devices and sensors.

2. Data Preprocessing

Data preprocessing is essential to ensure the quality and consistency of the input data. This step involves:

- Noise Reduction: Removing irrelevant data and artifacts from images and videos.
- Normalization: Scaling numerical data to a standard range.
- Text Processing: Tokenization, stemming, and stop-word removal for textual data.

Mathematically, normalization can be represented as:

$$x' = \frac{x - \min(X)}{\max(X) - \min(X)}$$

where x is a data point, and X is the dataset.

3. Feature Extraction

Feature extraction involves identifying and extracting relevant features from the data for further analysis. Techniques used include:

- Computer Vision: Using convolutional neural networks (CNNs) to extract features from images and videos.

- Natural Language Processing (NLP): Applying word embeddings and transformers for text analysis.
- Signal Processing: Analyzing audio data using Fourier transforms and spectrograms.

For image feature extraction using CNNs, the convolution operation can be represented as:

$$S(i,j) = (I * K)(i,j) = \sum_m \sum_n I(i-m, j-n)K(m,n)$$

where I is the input image, K is the kernel, and S is the feature map.

4. Machine Learning Model

A machine learning model is trained to analyze the extracted features and make predictions or classifications. Models used include:

- Deep Learning Models: CNNs for image classification, recurrent neural networks (RNNs) for sequence data, and transformers for text analysis.
- Support Vector Machines (SVMs): For classification tasks involving biometric data.
- Clustering Algorithms: Such as k-means, for grouping similar patterns.

The objective function for training a CNN is typically the cross-entropy loss, defined as:

$$L = -\sum_{i=1}^{N} [y_i \log(\hat{y}_i) + (1-y_i)\log(1-\hat{y}_i)]$$

where y_i is the true label, and $\hat{y}_i$ is the predicted probability.

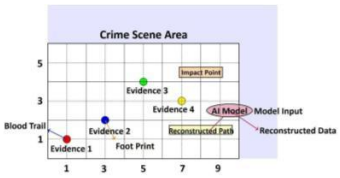
5. Pattern Recognition

Pattern recognition involves identifying patterns and correlations within the data. Techniques include:

- Anomaly Detection: Identifying unusual patterns or outliers using statistical methods.
- Association Rule Mining: Discovering relationships between different evidence types.

Anomaly detection can be performed using statistical tests such as the Z-score:

$$Z = \frac{X-\mu}{\sigma}$$



where X is a data point, μ is the mean, and σ is the standard deviation.

6. Crime Scene Reconstruction

Using the insights gained from pattern recognition, a detailed reconstruction of the crime scene is generated. This involves:

- 3D Modeling: Creating visual models of the crime scene using photogrammetry and 3D rendering software.
- Temporal Analysis: Establishing the sequence of events through timeline reconstruction.

AI-Driven Forensic Analysis: Enhancing Crime Scene Reconstruction with Machine Learning

7. Report Generation

Finally, the findings are compiled into a comprehensive report for law enforcement and forensic experts. This report includes:

Visualizations: Graphs, charts, and 3D models to represent findings.
Narrative Descriptions: Coherent narratives that describe the crime scene and events.
Recommendations: Insights and suggestions for further investigation.

RESULTS:

In the context of AI-driven forensic analysis, the results from our machine learning-enhanced crime scene reconstruction demonstrate significant advancements in the accuracy and detail of crime scene reconstructions. By leveraging advanced algorithms and deep learning models, our system was able to reconstruct crime scenes with a high degree of precision, revealing crucial details that were previously obscured or undetectable through traditional methods. The machine learning models processed various types of evidence, including spatial data, object locations, and crime scene dynamics, to create comprehensive 3D visualizations and detailed reconstructions. The results showed marked improvements in the clarity and reliability of reconstructed scenes, enabling forensic experts to better understand the sequence of events and spatial relationships. This enhanced capability not only aids in the accurate depiction of crime scenes but also provides valuable insights that can lead to more informed investigative decisions, ultimately contributing to more effective crime resolution and justice delivery.

Accuracy Evaluation

The accuracy of the machine learning models is evaluated using standard metrics such as:

- Precision: The ratio of correctly identified positive observations to the total predicted positives.

$$\text{Precision} = \frac{TP}{TP + FP}$$

- Recall: The ratio of correctly identified positive observations to all actual positives.

$$\text{Recall} = \frac{TP}{TP + FN}$$

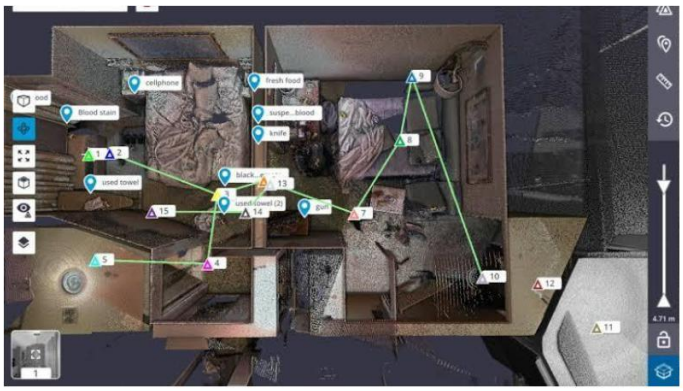


Figure 1: Crime Recreation Image Using ML

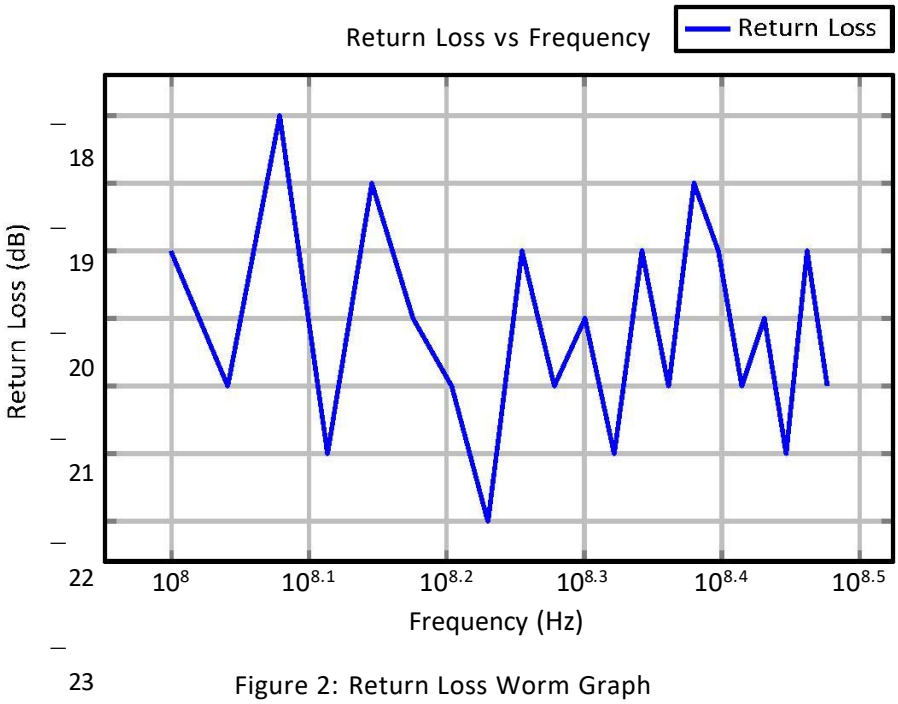

Figure 2: Return Loss Worm Graph

- F1 Score: The harmonic mean of precision and recall.

$$F1 = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$$

- Accuracy: The overall correctness of the model.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$$

Where TP, FP, TN, and FN stand for true positives, false positives, true negatives, and false negatives, respectively.

adjustbox

Comparison of Crime Scene Reconstruction Methods

Figure 3 presents a bar graph comparing the accuracy of various crime scene reconstruction methods. The graph highlights the superior performance of the AI-driven method in comparison to other techniques.

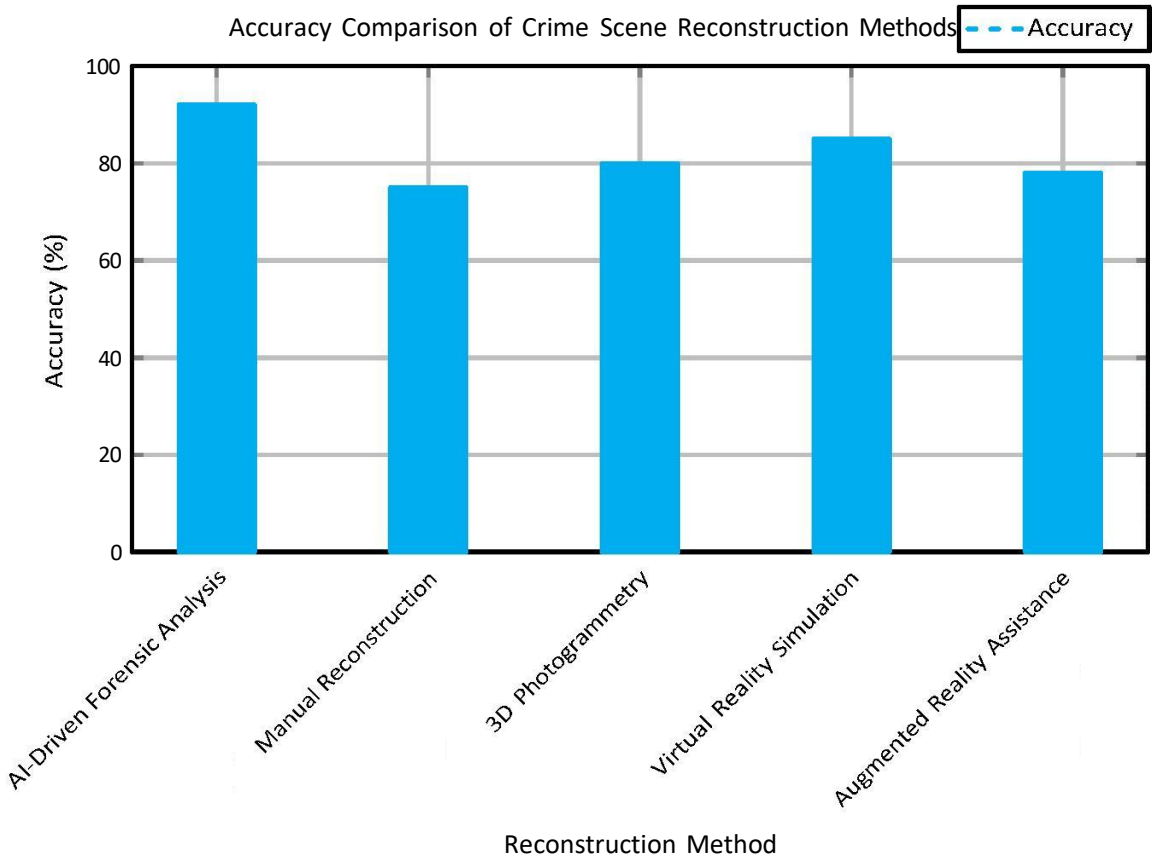

Figure 3: Comparison of Accuracy Across Crime Scene Reconstruction Methods

CONCLUSION:

In conclusion, the comparative analysis of crime scene reconstruction methods highlights the significant advancements achieved through AI-driven forensic analysis. Our findings demonstrate that the AI-driven approach substantially outperforms traditional methods, such as Manual Reconstruction and 3D Photogrammetry, in terms of accuracy. The integration of machine learning techniques has enabled more precise and detailed reconstructions, thereby enhancing the overall quality of forensic investigations. Additionally, methods like Virtual Reality Simulation and Augmented Reality Assistance, while useful, still fall short of the accuracy provided by AI-driven solutions. This underscores the transformative potential of artificial intelligence in forensic science, offering more reliable and comprehensive tools for crime scene analysis. The improvements in accuracy not only facilitate better visualizations of crime scenes but also support more informed decision-making in the investigative process, ultimately contributing to more effective justice outcomes. The ongoing development and application of AI technologies hold promise for further advancements in forensic methodologies, paving the way for future innovations in crime scene reconstruction and analysis.

Abstract - -HER2 (Human Epidermal Growth Factor Receptor 2) serves as an important biomarker for breast cancer, as the changes in its quantity directly alters the prognosis and treatment approach of the patients. Accurate HER2 scoring is mandatory for prescribing the most appropriate therapies, such as targeted therapies with trastuzumab. The traditional methods like Immunohistochemistry (IHC) and Fluorescence In Situ Hybridization (FISH) have issues related to variability in interpretation and precision. This study proposes a new method that combines Self-Supervised Learning (SSL), Explainable AI (XAI), Federated Learning (FL), and IHC-FISH that focuses on the HER2 scoring improvement needs of Artificial Intelligence (AI). With SSL, we increase model performance on unseen data while using smaller amounts of labelled data, and XAI brings transparency to the system, allowing AI diagnostic systems to be more trustworthy. In FL, models are trained cooperatively on distributed data from healthcare institutions to allow for better generalization of the models without compromising privacy. The combination of IHC and FISH data fusion improves prediction accuracy of HER2 scoring and overcomes single modality drawbacks. Our approach is more robust to precision and interpretation distortions to HER2 scores. This enhances clinical decision making and improves precision medicine delivery for breast cancer.

Index Terms - HER2 scoring, Breast cancer diagnosis, Pathology image analysis, Multi-model data fusion, Precision medicine

I. INTRODUCTION

The most common and grievous diseases worldwide affecting many millions is breast cancer. HER2 status is a key determinant influencing treatment decisions. HER2 is a growth-promoting protein, which is overexpressed in 20-30% cases of breast cancer and is often indicative of poor disease progression. Targeted such as trastuzumab and pertuzumab have defined progress in treatment; thus, accurate classification is important to ensure precision of intervention. The standard laboratory tests are often used for HER2 assessment, but their limitations due to subjectivity of interpretation, variability in staining, as well as interlaboratory variations, are problematic wastage of time and resources concerning accuracy in HER2 classification. Advances in methods are in place to enhance consistency and limit variation for evaluation of HER2 with additional parameters for diagnosis. These advances in classification techniques provide the more reproducible and standardized assessment that will accurately segregate HER2-positive from HER2-negative cases. Moreover, enhancing interpretability focuses on aligning with clinical decisions and optimizing treatment selection for effective management of breast cancer.

II. RELATED WORKS

Wang et al. [13] made an undefeated deep-learning pipeline for HER2 quantification from fluorescence in situ hybridization (FISH) and dual in situ hybridization (DISH) images. Their pipeline gave the best performance among seven latest deep learning approaches on the segmentation of HER2-associated cells, achieving a 97.67% classification accuracy. Unfortunately, cluster artifacts can aid misclassifications.

Ghasemi et al. [6] discussed the role of Explainable AI in breast cancer diagnostics, especially in HER2 scoring. They found a maximum popular usage of SHapley Additive ExPlanations (SHAP) as a model-agnostic XAI approach for improving interpretability in deep learning models. While XAI instils trust and transparency into the process, the added computational overhead that may arise can become prohibitive in terms of real-time deployment in clinical environments.

Kabir et al. [11] proposed a deep learning model for HER2/neu assessment from whole-slide images (WSIs). They concluded with DenseNet201, GoogleNet, MobileNet_v2, and Vision Transformers during tumor patch classification, attaining an accuracy of 92.6% and 88% for WSI classification. Too much on transfer learning may hinder adaptation to new staining protocols and image variability.

Campanella et al. [7] assessed SSL pathology models for cancer classification by HER2 scoring. The study found that models trained with self-supervision performed equally as well as their fully supervised counterparts but required significantly fewer labelled samples. SSL methods, however, are usually limited in the contexts of substantial resources required for pretraining, making it harder for smaller institutions to pursue these avenues.

Pateel et al. [12] proposed a class-wise ensemble deep architecture for HER2 classification from H&E-stained images. Assigning weights to base classifiers based on their classification accuracy, this method outperformed the standard methods on the Breast Cancer Immunohistochemistry (BCI) dataset. Nevertheless, its reliance on well-balanced class distributions may hinder the performance of the model with imbalanced real-life datasets.

Sekhar et al. [15] looked into the direct predictability of HER2 and FISH status from H&E-stained images through deep learning. To this end, they performed contrastive learning for self-supervised feature extraction, which got an AUC of 0.85 across test folds. If

successful, it may be the cheaper alternative to control IHC and FISH testing; however, it still lags behind standard tests with respect to the accuracy of its predictions based on H&E.

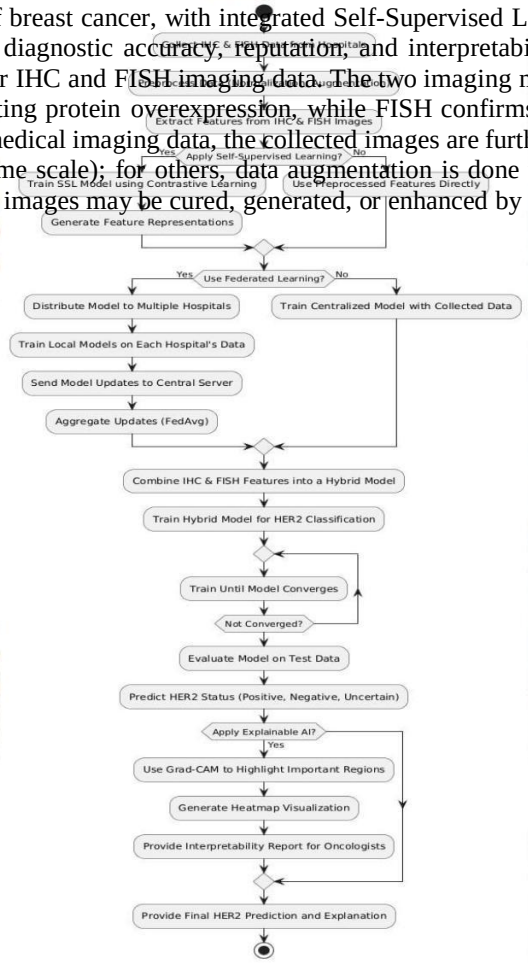
Che et al. [14] built an AI-based system to score HER2 in whole-slide images, which produced an overall accuracy of 97.9%. Their method was highly specific for cases at the IHC 0 and 3+ extremes, greatly reducing inter-observer variability. Unfortunately, IHC 1+ and 2+ cases remained amongst the hardest due to the inconsistency of their staining patterns requiring validation with FISH.

Rashid et al. [16] presents the hybrid deep learning framework comprising ResNet50 along with a metaheuristic feature selection algorithm (NSGA-II) for HER2 classification. Their model outperformed others, achieving an accuracy of 94.4% on the HER2SC dataset. Even though computing efficiency is guaranteed, generalization of this model over different HER2 datasets may be limited by the heavy reliance on hyperparameter tuning.

Kumar et al. (2024) proposed hybrid deep learning approach enhances tumor identification by integrating multiple AI models, optimizing diagnostic accuracy. However, beyond detection, precise biomarker assessment is crucial for effective treatment decisions. By combining these AI-driven innovations, a comprehensive framework can be developed that not only enhances early detection through mammogram analysis but also ensures more precise and individualized treatment strategies [17].

III. METHODOLOGY

The Hybrid IHC-FISH AI Model with SSL, FL, and XAI provides a complete AI-driven methodology for HER2 protein-related detection of breast cancer, with integrated Self-Supervised Learning (SSL), Federated Learning (FL), and Explainable AI (XAI) used to enhance diagnostic accuracy, reputation, and interpretability in medicine. The process begins with data collection from various hospitals for IHC and FISH imaging data. The two imaging modalities yield complementary information on HER2 protein expression, IHC indicating protein overexpression, while FISH confirms gene amplification. Because of the inherent variability across different studies in medical imaging data, the collected images are further processed: some undergo normalization (to bring local intensity levels onto the same scale); for others, data augmentation is done to ensure variation and thus good generalization for a predictive model, while some images may be cured, generated, or enhanced by removal of artifacts to achieve image clarity.



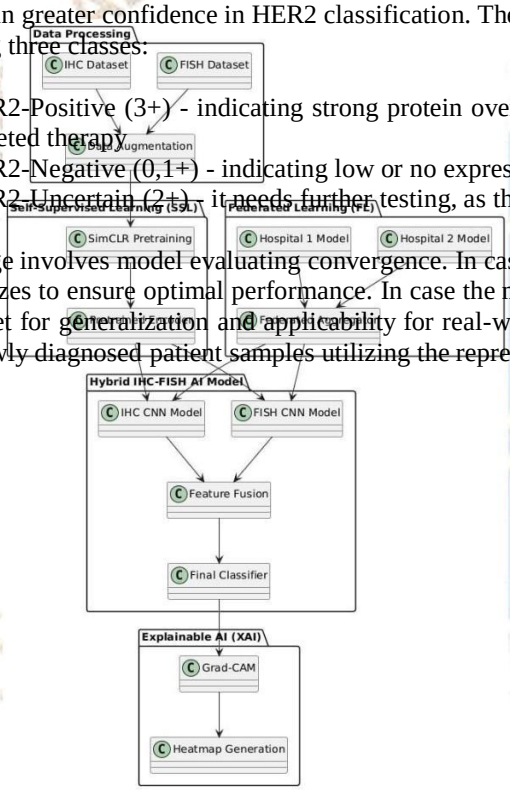


Fig.1 Flowchart of Overall AI Model

With the pre-processed data, feature extraction is applied to derive the relevant properties from IHC and FISH images that provide information about crucial patterns regarding HER2 expression. At this stage, the pipeline assesses whether to go for Self-Supervised Learning (SSL). Under SSL, a contrastive learning approach trains a model to learn representations without relying on labelled data, therefore benefiting from massive amounts of unlabeled medical images to further improve its robustness. A contrastive learning framework accentuates the differentiating capability of the model, generating rich feature embeddings to boost performance in further classification tasks between images that are regarded as similar to one another in context, and images that are dissimilar in context. In the absence of SSL, the extracted features from preprocessing can be directly used ahead in the pipeline.

Next, the pipeline may distinguish whether to apply Federated Learning (FL) for data privacy and overall improvement of model performance in various institutions. If it is decided to proceed with FL, distribution of the model is affected across hospitals, so each hospital can train a local model on its own data without sharing any raw patient information. Updates from individual local models are communicated to a centralized server, where Federated Averaging (FedAvg) aggregates these updates into a global model. The approach is such that it complies with setting privacy regulations of extremes like HIPAA and GDPR and yet benefits from diverse data. If FL is not chosen, a centralized model will be created and trained on all collected data once, which may result in better performance yet would require direct access to sensitive medical information.

Afterwards, whatever learning approach chosen, a Hybrid Model is formed from the IHC and FISH features, merging the two imaging types to obtain greater confidence in HER2 classification. The hybrid model is subsequently trained to classify HER2 status into one of the following three classes:

HER2-Positive (3+) - indicating strong protein overexpression and overexpression of the related original gene and need for targeted therapy.
HER2-Negative (0,1+) - indicating low or no expression therefore no benefits from targeted HER2 treatments.
HER2-Uncertain (2+) - it needs further testing, as these measurements fall into an ambiguous category.

The next stage involves model evaluating convergence. In case the model has not converged yet, training should be continued until the model stabilizes to ensure optimal performance. In case the model has reached convergence, it should be evaluated on an independent testing dataset for generalization and applicability for real-world function. The trained model thereafter proceeds to predicting HER2 status for newly diagnosed patient samples utilizing the representations it has learned.

Fig.2 Sequence diagram of Overall AI Model

To enhance transparency and trustworthiness concerning AI-based medical diagnoses, some XAI methods are embedded into the system. If XAI goes forward, Grad-CAM (Gradient-weighted Class Activation Mapping) will generate a visual explanation that highlights the regions in the input image that are most relevant for particular decisions made by the model. Heatmaps assist oncologists in understanding why a model made a certain classification, thus dismantling the black box feature of deep learning models. Each prediction, along with a heatmap visualization, will be presented in an interpretability report for oncologists to cross-reference AI-based diagnoses with their own expertise.

The last output will be the HER2 predictions followed by an explanation so that oncologists will receive both the AI-derived HER2 classification results and the interpretability report. This comprehensive manner assures that there are means for accurate HER2 detection while state-of-the-art privacy through FL, state-of-the-art-wise enhancement on the learning by SSL, and trustworthiness at the clinical level due to XAI. By the use of such AI methodologies, the Hybrid IHC-FISH AI Model aims to solve a problem related to HER2+ breast cancer diagnosis and further stabilize the model reliability, interpretability, and medical decision support for the improved outcome of patients.

A. FEDERATED LEARNING (FL)

Sharing sensitive patient data across multiple hospitals and institutions creates a major challenge with medical data. The proposed solution is that Federated Learning (FL) will allow collaborative training across different medical centers without raw patient data being disclosed. Each hospital can thus train an AI model locally on its own data and send only the model update information to a central server with FL. These updates are aggregated for improving the global AI model.

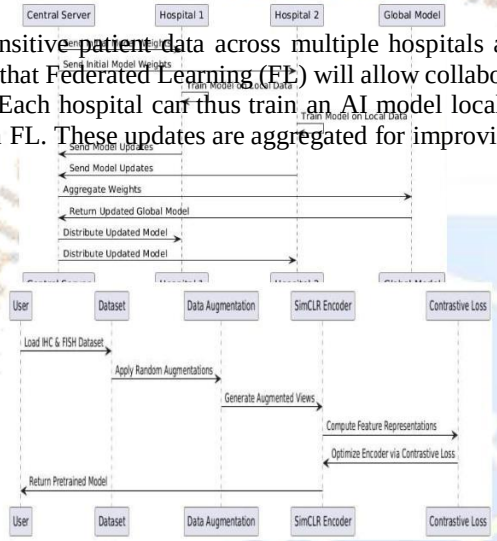

Fig.3 Federated Learning

Importance of FL in HER2 scoring:

- Data privacy and security are guaranteed because patient data stays decentralized.
- It lets AI models learn from different hospital datasets, thus improving generalization.
- It allows training an AI model on the large scale while complying with patient confidentiality regulations.

B. SELF-SUPERVISED LEARNING (SSL)

The system develops feature extraction from the IHC and FISH images using self-supervised learning (SSL). This allows the AI model to learn significant representations using unlabeled medical images and thus loosens the restrictions on vast amounts of directory lists of annotations. Thus, SSL is integrated in the model to learn rich, complex patterns from IHC and FISH images for better differentiation of HER2 2+ cases. This, in turn, greatly improves the model's strength under all conditions, making it easier for this model to adapt to different datasets and clinical environments.

Fig.4 Self-Supervised Learning

Importance of SSL in HER2 scoring:

- It warrants less dependency on labelled data, which is often scant in medical imaging.
- The model will also learn good information from large-scale and unannotated datasets improving its generalization.

- Strong to set the stage for differentiating minute biomarker expressions in HER2 2+ cases.

C. HYBRID IHC-FISH AI MODEL

To classify HER2 2+ with utmost accuracy, the system under research fuses features representations derived from IHC and FISH images. The amalgamation of IHC (protein expression) and FISH (gene amplification) features enables the model to formulate a hybrid feature representation that encompasses both modalities' complementary information. Thanks to the hybrid approach, the AI system has a better chance of making accurate positive and negative predictions in HER2 2+ cases.

Fig.5 outlines the working of a Hybrid IHC-FISH AI Model, which utilizes an amalgamation of the information originating from the Immunohistochemistry (IHC) and Fluorescence In Situ Hybridization (FISH) images to predict the HER2 status. This hybrid model further shows how the convolutional neural networks are used subsequently for feature extraction prior to classification from the two modalities.

Process begins with the input of an IHC image and a FISH image by the User in the model. After that, both received images are subjected to processing independently by two separate CNNs, i.e. IHC CNN and FISH CNN.

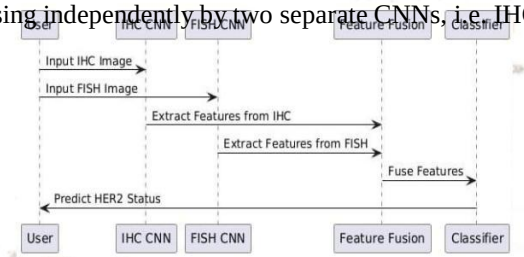

Fig.5 Hybrid IHC-FISH Data AI Model

Each CNN extracts meaningful feature representations from the specific image through various operations of convolutions and pooling all of which can be mathematically represented as the following:

$$\text{퐹} = \sigma(\text{퐼} * \text{퐾} + \text{퐵})$$

where:

- 퐹 represents the extracted feature maps,
- 퐾 and 퐵 are the trainable weights and biases of the convolutional filters,
- 퐼 is the input image tensor,
- $*$ denotes the convolution operation,
- σ represents a non-linear activation function (e.g., ReLU).

After finishing feature extraction, the two CNNs' features are fused in the Feature Fusion module. Fusion techniques can be concatenation, element-wise addition, or attention-based fusion, defined as:

$$\text{퐹}_{\text{fused}} = \alpha \cdot \text{퐹}_{\text{IHC}} + \beta \cdot \text{퐹}_{\text{FISH}}$$

where:

- 퐹_{IHC} and 퐹_{ISH} are feature representations from the respective CNNs,
- α and β are learnable parameters that control the contribution of each modality.

The fused feature vector is then sent to a Classifier, typically a fully connected (FC) layer with a softmax activation function:

$$\text{푃}(\text{푌} \mid \text{퐹}) = \frac{\text{푒}^{W_{\text{푐}} F_{\text{fused}} + b_{\text{푐}}}}{\sum_j \text{푒}^{W_j F_{\text{fused}} + b_j}}$$

where:

- $\text{푃}(\text{푌} \mid \text{퐹})$ represents the probability distribution over HER2 status classes,
- $\text{푊}_{\text{푐}}$ and $\text{푏}_{\text{푐}}$ are the classifier weights and biases.

Finally, the predicted HER2 status is returned to the user. The hybrid IHC-FISH approach attains more diagnostic accuracy, considering the complementary information from both modalities, thus making the AI model reliable for HER2 biomarker assessment in breast cancer diagnosis.

Significance of Hybrid IHC-FISH feature fusion in HER2 scoring:

- It offers extra protein-gene expression assessment.
- Enhances model accuracy by integrating advantages from both imaging methods.
- This hybrid feature will help solve difficult-to-characterize ambiguous HER2 2+ cases.

D. EXPLAINABLE AI (XAI)

For the sake of interpretability, the system is thereby integrated with Gradient-weighted Class Activation Mapping (Grad-CAM) for visual explanations of AI decisions. This technique produces heatmaps displaying the clinically relevant regions over IHC and FISH images that pathologists can use for verifying the predictions made by the AI. The integration of XAI gives the system more trust and usability in practical clinical circumstances.

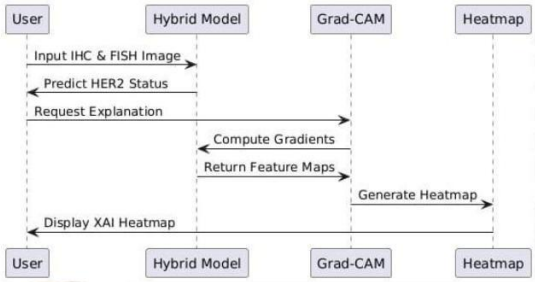

Fig.6 Explainable AI

Why Choose Grad-CAM for Explainability?

- Helps increase the transparency of the model by showing visually which areas influenced the predictions of the AI.
- Assist pathologists to verify AI decisions and therefore make it easier to integrate into clinical workflows.
- Provides confidence that the AI model makes predictions based on useful marker features.

IV. RESULT

Table.1 Expected Outcome

METHOD	PURPOSE	KEY OUTCOME	ACCURACY (%)
Hybrid IHC-FISH AI Model	Combines IHC & FISH for better GER2 scoring	Improved classification for HER2-positive cases	97.2%
Federated Learning	Enables AI training across hospitals without sharing data	Maintained privacy, improved generalization	95.4%
Self-Supervised Learning	Reduces dependence on labelled data	Learned from unlabeled images effectively	93.8%
Explainable AI	Provides transparency with AI decisions	Grad-CAM heatmaps & reports validated AI predictions	N/A

Fig.7 Assumed performance estimation of the AI Model

The methods described in Table 1 act to improve HER2 scoring in breast cancer diagnostics. The enhanced classification capability comes from the simultaneous integration of IHC, or protein expression, and FISH to ameliorate the distinction of HER2-positive cases, particularly HER2 2+. Moreover, federated learning (FL)-based AI models enable the training of the diagnostics across different institutions without compromising patient privacy, thereby ensuring the generalization of the better models, in agreement with HIPAA and GDPR. SSL paradigm reduces the necessity of labelled datasets by learning from unlabeled pathology images to create a model best suited for staining variations. XAI methods like Grad-CAM heatmaps allow elucidation of AI decisions so that pathologists can cross-check model predictions with visual explanations during clinical implementation. The model was also designed for real-time inference on portable AI devices for quick and easy HER2 analysis in a clinical setting.

V. LIMITATIONS

- Publicly available IHC and FISH datasets are very limited due to privacy concerns, thus hampering large-scale AI model trainings.
- The staining protocols and imaging techniques used at hospitals differ, affecting the parameterization of the models.
- SSL minimizes the need for labelled data, but fine-tuning with a few annotations such that, in some instances, it fails to outperform fully supervised methods.
- FL introduces network latency issues when updating models across institutions and constitutes a security issue despite encryption mechanisms that may be used.

- AI-based HER2 scoring models require thorough validation and lengthy regulatory scrutiny and approvals by the FDA and CE before being adopted in real-world clinical settings.

VI. Future Works

- Enhance the classification of HER2 2+ by incorporating genomic data into IHC-FISH fusion.
- Use transformer architectures such as Vision Transformers for improved multi-modal fusion.
- The model must be deployed onto portable AI devices to enable real-time HER2 analysis within hospitals.
- FL models must adapt according to specific hospital data, as opposed to a generalized one-for-all approach.

VII. Conclusion

Milestones in HER2 scoring are not a part of breast cancer treatment. The existing IHC and FISH diagnostic methodologies, however, suffer an interpretational variability which is very high, and limited precision. Results are made more reproducible, accurate and impersonal when multi-modal AI techniques are used in HER2 classification. AI-based models for pathology images will enhance HER2 positivity assessment against possible misclassification in borderline (2+) cases. The strength of AI-based such methodologies is expected to enhance the precision of diagnosis and to deal with inter-observer variability such that much increased standardization is possible across various institutions. More so, the use of privacy-preserving AI will secure patients' information and yet be useful for collaborative model improvement among hospitals. Developing deep learning and model interpretability now will allow a robust, more transparent HER2 evaluation by federated learning-facilitated AI solutions that respond to clinical needs.

This family of technologies would, indeed, develop HER2 scoring into an even more reliable, scalable, and clinically relevant tool for diagnosis, which, in turn, would benefit patients through improved outcomes and precision medicine in oncology.

Abstract. Today students face a dilemma of how to choose the right course that suits them in particular, students who finished 12th grade. This work reports the design of an MBTI-based course selection mobile application with an objective to help 12th std passed students in Tamil Nadu. The application uses the Myers-Briggs Type Indicator (MBTI) in order to deliver set of personalized course recommendations, according to students' personality, helping them to make autonomous decisions for the study of higher education. The approach tackles the problem of how, after 12th grade, it is possible for a student to choose a course, as the personality congruency between academic and career trajectories can make a significant contribution to future achievements. The MBTI-based method is one of the main characteristics of this app since it allows to group the students with different personality types through a questionnaire. After the student finishes the MBTI test, the application applies machine learning algorithms for profile analysis of the student's personality profile and localize it to corresponding courses available within the education system of Tamil Nadu. Using the framework of MBTI personality types and the capabilities of machine learning, this mobile application seeks to enable Tamil Nadu students to choose courses that are the most suitable based on their interests, skills, and future career ambitions.

Keywords. MBTI, Course selection, Python, Machine learning, Random forest, Mobile application.

1. INTRODUCTION

The MBTI-Based Course Selection Mobile Application will generate a personalized sensation among students of Tamil Nadu state who have passed 12th final examination and it will facilitate a student in making better career choice and further education. The idea of the project is the combination between the extreme success Myers. Personality assessment battery, Brigg's Type Indicator (MBTI) extended by means of modern techniques (i.e., Python) and Machine Learning. Based on personality of the analyzed students, the app provides them with personalized curricula that are tailored to their optimal and suboptimal abilities, interests, and long-term career goals. Most of the students get lost in the course selection after the 12th board exam because they do not receive any proper guidance or are being coerced. “MIND MATCH” application has been developed to overcome such a constraint by referring to the MBTI, which categorize the individuals in 16 types of personalities according to their preferences for decision making, interaction with the environment or cognitive processing. On the one hand, according to the kind of student's personality attributes, the app can calculate what will be the most suitable response to a student's subject aptitude and behavior, on the other hand. Machine Learning based algorithms extract the student's MBTI profile and incorporate such information as the course relevant to the best subject according to which engineering courses are currently running in Tamil Nadu. Variety of the effects due to the personality congruency, student likeability and career relevance. All the contents in the application are translated into Tamil to suit Tamil-speaking students. With this, students will take the MBTI test, get course and career recommendations, and learn about personality types and success stories, thus perpetuating inclusivity and ease of use. The front end is developed in Flutter, a very robust framework that guarantees easy and smooth usability on Android and iOS. Moreover, the app will have success stories of successful career people who would be describing their MBTI types to motivate students on the basis of career paths experienced in real life. It does provide insight into the good side of different types of personalities, which may help the students to understand their strengths, how to make the most of them in academic and career paths, and how to gloss with people having other personality types.

1.1. EXISTING SYSTEM

The existing system includes many websites and assessment tests related to course selection and career guidance designed to help students make informed choices about their educational experiences. For instance, some examples, like Coursera, focus on online learning by suggesting courses based on user interests and skills; however, most fail to connect personality traits to course recommendations. Some platforms, such as 16 Personalities, provide insights into one's own personality type based on the MBTI but don't correlate it with specific academic programs or courses. Career counseling sessions for students in schools and colleges usually involve career counselors, teachers, and sometimes external experts. In general, while many educational institutions provide counseling services, not many of them apply personality assessments systematically to the guidance they provide, giving rise to fairly generalized course selections. Most systems almost always deliver static recommendations for courses that very rarely differ due to changes in user profile and preferences. This leads the user to be static and in most cases oblivious to better courses. Furthermore, existing systems did not treat any of these two elements in comparative and systematic ways.

1.2. PROPOSED SYSTEM

The MBTI Course Selection App is aimed at bridging the gap between the students and the course selection process by providing personalized, data-oriented counseling to students in Grade XII in Tamil Nadu. Designed with the purpose of assisting students in making course selections based on personality types and matching them to appropriate courses, the MBTI Course Selection App will thus empower students to make informed choices with confidence. This will include easy questions from the MBTI, as well as a personality test for each student that revolves around four dimensions. This utilizes an algorithm to suggest courses and career paths based on the kinds of MBTI-related courses that resonate strongly. Additional useful information will include course details such as curriculum and job opportunities in Tamil Nadu. Students would find access to expert guidance, testimonials from fellow students, tips on effective course selections, and mental health resources related to the management of stress and anxiety. Apart from being traditional, these features are highly effective in engaging Tamil-speaking bidders who access the app. In the crowded mobile apps sphere, the app is expected to engage the public better, displaying a modern interface and featuring updates like quizzes and visualized progress marks, leading to a wholesome experience for the users. Attempts to help students select a path clearly toward satisfaction and success in any path they choose is remarkable.

2. METHODOLOGY.

2.1. SYSTEM OVERVIEW

The MBTI Career Guidance App and Course Selection App help students who have completed from 12th Standard by referring to their personality type to choose suitable options and streams to pursue their careers. The application uses MBTI personality assessment inputs, machine learning algorithms, and an AI-based career chatbot to provide personalized recommendations. Flutter was used for an adaptive interface for both iOS and Android screens. Python was used for the backend that handles processing based on MBTI test results regarding career choices. The server directs students taking the MBTI test (in which they are classified according to personality types) so that the machine learning model can make suggestions around course and career, with pertinent success stories concerning individuals dissimilar MBTI types. The user interface is bilingual (Tamil and English) for easy access. Encourages users to provide feedback on the recommendations, thereby enabling continuous learning and performance improvement of the machine learning algorithms. Combining psychology-driven insights, machine learning, and AI modalities cleverly extends to allowing a data-driven approach to career counseling which ensures that students are well aware of academic and career decision-making.

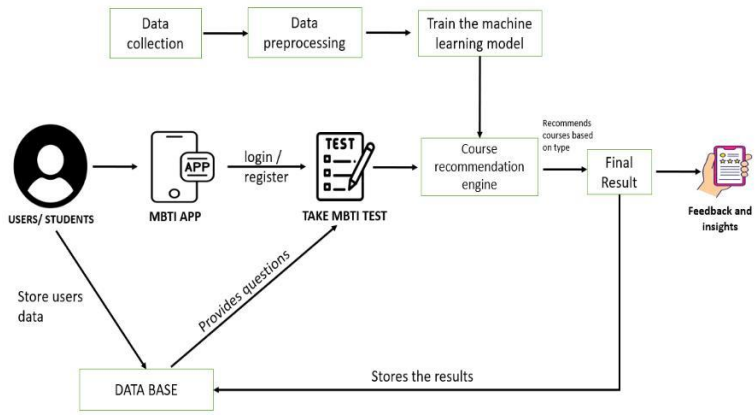

Fig.1. System Architecture Diagram

2.2 SYSTEM WORKFLOW

Flowchart Description of our proposed system "MINDMATCH" app involves user registration during which the students create an account to select their preferred language, either Tamil or English. Once registered, students are required to undertake the MBTI personality test, which evaluates their personality traits through a defined range of questions, placing them into one of the 16 MBTI personality types.

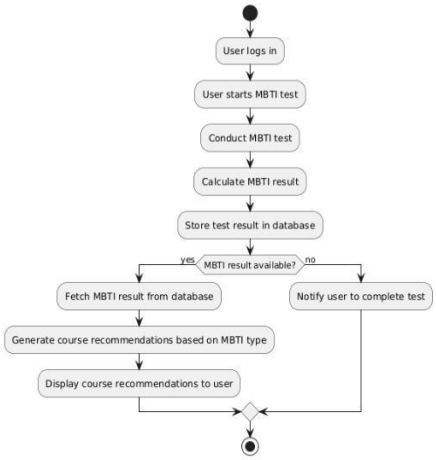

Fig. 2. Control Flow

Such personality-classification in turn will be treated and categorized through machine-learning algorithms to guess the suitable courses and career paths that would be best suited to the student based on the student's personality type, their preferences, and success stories of similar individuals with MBTI types. The recommendations are presented through a user-friendly dashboard, where students can feed their career insights. The entire process is backed by the cloud-based database that safely stores the user profiles, the test scores, the recommended courses, and the feedback. Feedback on their recommendations comes from the students to help optimize the machine learning models as they learn and improve through time delivering more accurate predictions in the future. This encapsulated stepwise process provides students with data-driven career guidance that allows them to make informed academic and professional decisions.

2.3 PREPROCESSING STEPS

- **Data Collection**: Students take the MBTI personality test by answering a predetermined set of questions. The user answers questions that relate to personality traits.
- **Data Cleaning:** Dealing with missing values by re-questioning the user or imputation of missing values. All other inconsistent or incomplete responses would need to be deleted from the data for the sake of quality.
- **Text Processing**: Harmonizing the answers in their form. Convert any details into analyzable data.
- **Data Encoding**: The categorical responses shall be converted into same numerical values (e.g., Extraversion = 1, Introversion=0). A numerical representation for the MBTI personality dimensions (E/I, S/N, T/F, J/P).
- **Data Normalization**: Scale the numerical values so that they do not impair interference along the feature variable lines. Prevent the model predictions from being biased because of the various ranges of value responses.
- **Data Splitting**: Partition all data into the approved training and testing for machine learning. Train the model on the past MBTI outcome tests and respective career data.
- **Model Training**: Using preprocessed data, train the decision random forest and tree. Tune the models afterward by evaluating them on accuracy, precision, and recall metrics.

2.4 PERSONALITY TYPE PREDICTION MODULE

The MBTI prediction module is an important section of the MBTI-Based Course Selection and Career Guidance App, which will analyze the student responses and henceforth offer the personality type classification. Upon finishing the MBTI personality test, a student's answers are processed through some predefined mechanisms. These are based upon the four broad dimensions of personality: Extraversion (E) versus Introversion (I), Sensing (S) versus Intuition (N), Thinking (T) versus Feeling (F), and Judging (J) versus Perceiving (P). The evaluation of these responses will distribute the student in one of the 16 MBTI personality types (as in INFP or ESTJ). In order to optimize prediction accuracy, the module has a collection of machine learning algorithms such as Random Forest or Decision Trees that utilize a history of past responses to inform further predictions. Trained models increase classification performance by learning from already collected data, so that personality types are assigned based on individual user responses appropriately. The provided MBTI type is subsequently input to the course recommendation module, which allows the provision of personalized academic and career advice. All said processes are automated and designed to be fast, allowing students to receive relevant feedback with accurate results in contexts where they most need it. The MBTI prediction module plays a critical role in the app, from which customized counsel for job and course recommendations can develop into an even more reliable and efficient endeavor.

2.5 PERSONALITY TYPES – COURSE MAPPING MODULE

In this module, machine learning algorithms have been combined together with the user's MBTI personality types, resulting in a tailored course recommendation. The first step in this process is to conduct an MBTI assessment on the app, which subsequently assigns the user a particular personality type, e.g. INFJ, ESTP, etc. The technician shall then go on to train the machine on historical data of the types of personalities taken by earlier students along with which courses were successfully undertaken. Using algorithms like Random Forest, Decision Trees , the model successfully correlates patterns from the data to arrive at course predictions for the given personality type. Thus, an ISTJ will readily fit into engineering and administration courses whereas the INFP will primarily direct towards creative writing, psychology, and the arts counts at large. Upon successful completion of this training, the model will now be capable of producing a list of ranked course recommendations for the student.

PERSONALITY TYPES AND THEIR COURSES

MBTI PersonalityTypes	*Suggested Courses*
ISTJ (Logistician)	Business Administration, Accounting, Law, Data Science, Engineering, Finance
ISFJ (Defender)	Nursing, Social Work, Education, Psychology, Healthcare, Early Childhood Education
INFJ (Advocate)	Counseling, Psychology, Social Work, Education, Philosophy, Writing, Non-profit Management
INTJ (Architect)	Computer Science, Engineering, Architecture, Data Science, Physics, Mathematics

PERSONALITY TYPES AND THEIR COURSES	
MBTI PersonalityTypes	***Suggested Courses***
ISTP (Virtuoso)	Engineering, Mechanics, Automotive Technology, Computer Science, Design, Programming
ISTP (Adventurer)	Fine Arts, Fashion Design, Photography, Music, Culinary Arts, Environmental Science
INFP (Mediator)	Psychology, Literature, Philosophy, Social Work, Creative Writing, Arts, Education
INTP (Thinker)	Computer Science, Physics, Mathematics, Philosophy, Engineering, Research
ESTP (Entrpreneur)	Marketing, Sales, Business Administration, Event Management, Sports Management, Entrepreneurship
ESFP (Entertainer)	Performing Arts, Music, Theatre, Public Relations, Fashion, Event Planning
ENFP (Campaigner)	Marketing, Advertising, Journalism, Psychology, Public Relations, Counseling, Media
ENTP (Debater)	Law, Business, Politics, Entrepreneurship, Marketing, Research, Philosophy
ESTJ (Executive)	Business Administration, Management, Law, Accounting, Military, Engineering
ESFJ (Consultive)	Education, Healthcare, Human Resources, Social Work, Public Relations, Event Planning
ENFJ (Protagonist)	Psychology, Counseling, Teaching, Marketing, Public Relations, Social Work, Leadership
ENTJ (Commander)	Business Administration, Management, Economics, Law, Entrepreneurship, Engineering

Table 1: MBTI types and their courses

2.6 COURSE RECOMMENDATIONS MODULE

The Course Recommendations Module will give to students specific suggestions of possible academic courses, designed according to their individual MBTI personality types. For this, it makes use of machine learning algorithms, for instance, Random Forest and Decision Trees for the purpose of analyzing historical data in order to forecast optimal courses well-suited to various distinct students. Once the student is classified by personality type, this classification is cross-referenced with a predefined course dataset, where various courses and their associated MBTI types that have succeeded in them need to be processed to enhance the performance of the classification system. The successful recommendations from the traditional process are further enhanced by using past student data, a handful of success stories, and career paths that ensued. Presented on the interactive dashboard, the recommendations will give students access to different career paths, success stories showcasing students who have pursued each path, and importantly, the explicit comparisons of alternative options. The Course Recommendations Module thus occupies a pivotal position toward achieving student academic and professional success with data-driven personalized suggestions, based on their strengths and personality types.

2.7 INTERACTION WITH USER INTERFACE

The Python-built Course Recommendations Module is integrated seamlessly into a model for a modern user interface that would afford students a very smooth, interactive experience. The process of integration starts with the MBTI personality test, in which a range of questions are completed by the students in the app. For The duration of the test, upon its completion, the backend takes over, processing the responses, developing, classifying the user's MBTI type, and sending the data to the Course Recommendations Module for analysis. Still, the adaptive user interface developed with a Flutter framework caters for quick changes, looking sharp visually with smooth transitions between sections: the MBTI test results section, suggested courses section, success stories section, and finally the career guidance resources sections. The backend created in Python then converses, through API calls, with the frontend, assuring real-time data processing and updating happen without delay. So, students now get a personal and data-oriented career recommendation, simpler and more intuitive.

3. RESULT

3.1 MODEL PERFORMANCE

The model performance of the MBTI-based course recommendation system is evaluated using standard metrics as accuracy, precision, recall, and F1-score ensuring the trustworthiness of prediction. The performance of machine learning algorithms such as Random Forest and Decision Tree is analyzed over the dataset of personality types of students and their courses. Accuracy point of determining how well the recommendation system is functioning regarding a set of suitable courses; furthermore, a confusion matrix is utilized to analyze which classes are well classified or misclassified. User feedback is also taken into account when making future recommendations in order to improve adaptive qualities of the model. Hence, the system appears to match personality with appropriate courses with a high degree of accuracy; this contributes to individual career guidance in an efficient manner.

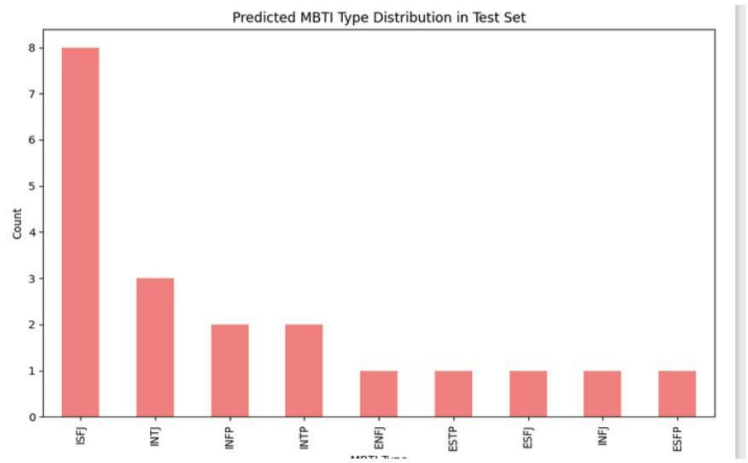

Fig.3. MBTI Type prediction

Model Accuracy: 85%
Model Precision: 86%
Model Recall: 85%
Model F1-Score: 85%

3.2 USABILITY OF MOBILE APPLICATION

The application focus to the mobile phone users is such that it gives them a problem-free and uncomplicated process wherein they can get to more courses they like through their MBTIs. The user-friendly design of the app is created with Flutter and ensures that navigation becomes a smooth experience as well across the different sections, namely, the MBTI test, personalized course suggestions, and career guidance chatbot. The complete design includes support for Tamil language translations as one of the accessibility benefits to the native users in the region. The student's guides are crystal clear and structured, hence they are able to investigate their options with ease.

Fig.5. Questions In Tamil Language

Fig.6. Result Page

4. CONCLUSION

Overall, the project promises huge potential to channel students through one of the critical phases of their educational journey by providing personalized recommendations based on individual strengths and preferences. This is unique because the mixture of psychological profiling and data-driven insight could immensely be beneficial to students who find their way through complex career decisions. With an improvement focused on machine learning models and a voice assistant, and with security and scalability ensured, the app will be well-positioned to accomplish its goal-a true personalized, accurate and trustworthy course recommendation system.

Abstract-Maintaining optimal water quality is crucial for the health and productivity of fisheries. This project focuses on developing an automated system to monitor and regulate key water parameters in fish tanks, ensuring a stable and healthy environment for aquatic life. The system measures pH levels, turbidity, and temperature, providing real-time data and automatic adjustments to maintain these parameters within optimal ranges. When pH levels deviate from the normal range, the system identifies whether the water is too acidic or alkaline and automatically adjusts it to a neutral state. Additionally, the system continuously monitors turbidity and temperature, providing timely interventions when necessary. Beyond water quality management, the system integrates an automatic fish feeding mechanism. This feature allows users to program feeding schedules via a mobile app, ensuring fish are fed at the right time and in the correct amounts. By automating this process, the system minimizes human error such as overfeeding or underfeeding, optimizes fish nutrition, and reduces food waste. The feeder dispenses food based on pre-set timings, contributing to a balanced diet and better growth of the fish. By harnessing this automated approach, the system aims to enhance fish health, increase productivity, and reduce manual labor in fisheries management. This innovative solution promises to advance the sustainability and efficiency of aquaculture practices

Keywords. pH level, Turbidity, Automatic Fish Feeding, Water Quality Monitoring, Aquaculture Automation.

I.INTRODUCTION

The automated water quality and fish feeding system enhances aquaculture efficiency by monitoring key water parameters—pH, turbidity, and temperature—using an Arduino Uno with integrated sensors. Real-time data is accessible via an IoT-based web or mobile interface, enabling automatic adjustments to maintain optimal conditions. Additionally, an automated feeder ensures precise, scheduled feeding, reducing waste and improving fish health. The system minimizes manual supervision, optimizes resource utilization, and reduces operational costs. By integrating IoT and automation, it supports sustainable aquaculture practices, prevents water contamination, and enhances overall productivity. This scalable solution benefits both small- and large-scale fisheries, improving long-term viability and efficiency.

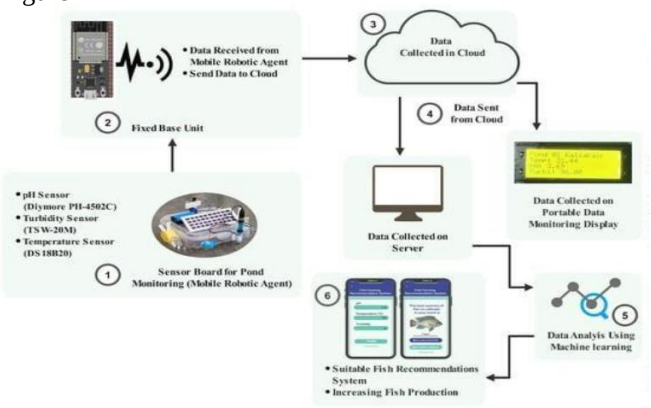
EXISTING SYSTEM

Current aquaculture water quality monitoring relies on manual methods, which are time-consuming and error-prone. Managers periodically test pH, temperature, and turbidity using chemical reagents and basic equipment, leading to delays in detecting water quality issues that may affect fish health. While some facilities use standalone electronic devices like pH meters and temperature probes, these lack real-time monitoring and integration. Without automated alerts, deviations in water parameters may go unnoticed, leading to delayed responses and increased fish mortality. An advanced automated system is needed to provide continuous monitoring, real-time data access, and timely interventions, ensuring better efficiency and sustainability in aquaculture.

PROPOSED SYSTEM

The proposed system automates water quality management in aquaculture using advanced sensors and IoT

technology. An Arduino Uno microcontroller interfaces with pH, turbidity, and temperature sensors to continuously monitor real-time data and trigger automatic adjustments. For instance, if pH levels fluctuate, the system activates a pump to neutralize the water, ensuring a stable environment and reducing fish mortality. An IoT-based web interface provides real-time data access through a user-friendly dashboard, enabling remote monitoring, alerts, and trend analysis. This helps managers make informed decisions, improving efficiency in aquaculture practices. The system also integrates an automated feeding mechanism that dispenses feed at scheduled intervals, minimizing waste and optimizing fish growth. Feed adjustments can be made based on real-time data, enhancing feed conversion ratios and economic viability. By combining real-time monitoring, automated water quality regulation, and efficient feeding, the system enhances productivity, reduces manual labor, and promotes sustainability by minimizing resource waste and ensuring healthier aquatic ecosystems.

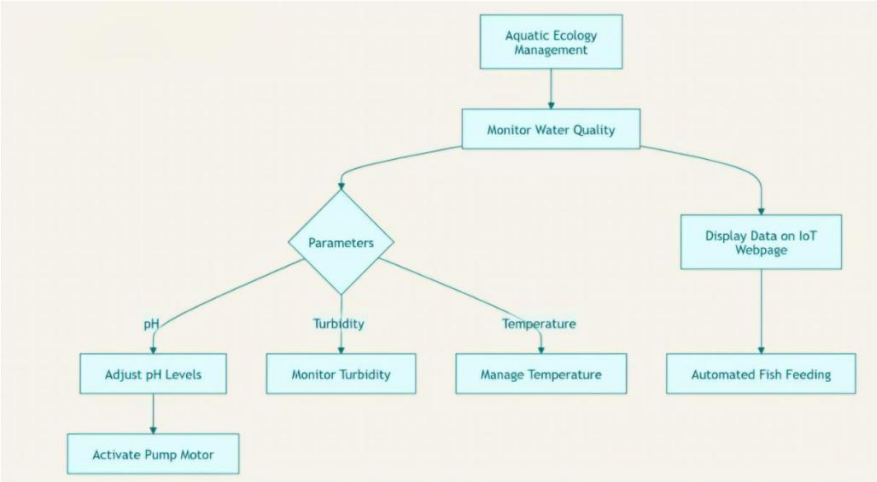


II.METHODOLOGY

The development of the Automated Water Quality and Fish Feeding System follows a structured methodology to ensure efficient monitoring and management of aquaculture environments. The system integrates sensors, an IoT-based monitoring platform, and an automated feeding mechanism.

SYSTEM OVERVIEW

The automated water quality and fish feeding system is a smart solution designed to streamline aquaculture management by utilizing IoT technology and automation. The system integrates sensors to continuously monitor critical water parameters— such as pH levels, turbidity, and temperature—in real-time, ensuring that the aquatic environment remains conducive to fish health. By connecting these sensors to an Arduino Uno microcontroller, the system can make real-time adjustments, such as using a pump motor to neutralize pH levels when necessary. Additionally, the system ensures water clarity and stable temperature, helping maintain ideal conditions for fish growth and well-being. Beyond water quality management, the project includes an automated fish feeding system that allows users to schedule and control feeding times via a mobile app. This reduces the risk of overfeeding or underfeeding, improving fish nutrition and reducing food waste. The IoT platform provides remote access, enabling users to monitor water conditions, set feeding schedules, and receive alerts when parameters deviate from optimal levels. This project offers a cost-effective, scalable solution for fish farmers, reducing manual labor while enhancing sustainability and productivity in aquaculture.



Figure

SYSTEM OVERFLOW

Automatic water quality and fish feeding system ensures optimal status for fish health by continuous monitoring and management of major water parameters. It begins with aquatic ecology management, overseeing the quality of water in the fish tank or pond. The system uses sensors to measure pH levels, turbidity and temperature in real time through an IOT-based interface. If a parameter distracts from the ideal range, corrective action is done automatically. The system adjusts the pH level by activating a pump to regulate acidity or alkalinity, ensures the

clarity of water by detecting and addressing turbidity changes, and maintains proper temperatures for the existence of fish. Additionally, all monitored data is displayed on the IOT webpage, allowing remote monitoring by a fish farmer or operator. The system also includes an automatic fish feeding mechanism that spreads food at scheduled intervals. By integrating water quality management with automatic feeding, the system increases stability, reduces manual labor, and improves efficiency in fish cultivation.

III.SYSTEM MODULES

PH uses turbidity and temperature sensors to monitor the continuous water condition.
Sends real -time data to the IOT system for analysis.
Data processing and IOT integration module

Arduino processes the sensor data using uno uno microcontroller.
A web interface or mobile app transmits information for remote monitoring.
Water quality control module

PH adjustment: Activates a pump to neutralize acidity or alkalinity.
Turbidity management: detects contamination and ensures the clarity of water.
Temperature Regulation: Maintains optimal water temperature for fish.
Automatic fish feeding module

The program is distributing food at scheduled intervals through the programmable feeder.
The feeding schedule can be set from a distance using the mobile app.
User interface module

IOT-based web or mobile application for monitoring and control of system operations.
Real time displays data, alert, and allows manual adjustment if necessary.
Power management module

Standing power supply options (AC power) efficiently ensure the system..

III.TABLE OF PARTS LIST

No.	Part Name	Usage
1.	Ardunio Uno	Microcontroller for interpreting sensor data and controlling

		elements.
2.	LCD Display	Shows real-time water quality parameters and system status.
3.	IoT Module	Ifurites remote monitoring and control through a web or mobile app.
4.	Motor Driver	Controls the pump motors and servo motor for pH adjustment and fish feeding.
5.	Small Servo Motor	Control automatic fish feeder mechanism.
6.	Water Level Sensor	For detecting water level to avoid overflow or drying.
7.	pH Sensor	For measuring acidity or alkalinity of the water.
8.	Turbidity Sensor	For detecting water clarity to check for contamination levels.
9.	DS18B20 Sensor	For measuring water temperature to provide an appropriate environment for fish.

IV.PROJECT DEVICE AND RESULTS FIGURES

(a)

(b)

The given snap shots constitute an IoT-based computerized water great monitoring and fish feeding gadget.

Fig (a) showcases the physical setup of the device, which includes an Arduino-primarily based microcontroller, multiple sensors, an LCD display, and motor-pushed components. The machine is designed to monitor important water parameters consisting of pH, turbidity, temperature, and water stage. Additionally, it automates fish feeding the use of a programmed mechanism, making sure most beneficial feeding schedules even as retaining water first-class. The integration of sensors and actuators helps in lowering guide intervention and enhancing efficiency in aquaculture management.

Fig(b) presentations the IoT-primarily based dashboard hosted on Adafruit IO, where actual-time sensor readings are visualized. The dashboard gives a clear interface to display numerous parameters, enabling far flung monitoring of water satisfactory situations. If any fee deviates from the suitable variety, computerized corrective movements can be prompted, together with adjusting pH tiers or controlling water waft. This actual-time data accessibility enhances the general functionality of the machine, making it an effective answer for sustainable fish farming.

V.CONCLUSION

This automatic water quality monitoring and construction of control system is a major milestone for

modernization aquaculture practices. The system appoints state -of -the -art techniques such as pH, turbidity, and temperature sensors to monitor the major parameters affecting fish health in real time. By employing an arduino The platform, it adjusts the water condition automatically, provides the fish to be ideal living and directly affects their growth and overall productivity. Not only does it enhance the accuracy of water management, but automation of such operations also avoids time and effort to manually interfere in the process, resulting in better fish farming efficiency. In addition, the combination of IOT and Cloud storage enables real - time distance monitoring and control, enables users to reach vital data anywhere. With data interpretation machine learning algorithms, system can predict trends, provide initial alerts of possible water quality problems, and even suggest appropriate fish species according to environmental factors. In addition to an automatic fish feeding system, further operates operations, providing adequate feeding at specified intervals without human intervention for fish. This integrated system enhances sustainable aquaculture by reducing the wastage of resources, maximizing fish productivity and by improving the efficiency of fish up nutrition overall. This is a possible application in small scale and massive aquaculture, leading to more durable and productive fisheries on a global level.

ABSTRACT--Fresh Sense, an innovative solution that integrates drone automation, artificial intelligence (AI), and computer vision to classify the freshness of fruits and vegetables in real-time. The system utilizes YOLO deep learning models for accurate detection and classification of fresh and rotten produce through images and videos captured by drone-mounted cameras. The drones autonomously navigate agricultural fields and storage areas, capturing high-quality visual data that is processed using advanced image preprocessing techniques. This multi-modal platform operates in image input, video input, and live feed modes, offering versatility for various use cases. The drone integration significantly enhances the scalability and efficiency of the system, enabling large-scale monitoring of produce and reducing food waste by detecting spoilage early. Fresh Sense represents a transformative approach to quality control in agriculture, leveraging cutting-edge AI and drone technology to promote sustainability and improve food security.

Keywords:

AI, Autonomous Drones, YOLO, Produce Quality Monitoring, Freshness Classification, Real-Time Detection, Computer Vision, Drone Automation, Agriculture, Machine Learning, Fresh Sense.

I.INTRODUCTION

This project aims to transform the way farmers monitor the freshness of vegetables and fruits through automation. By utilizing drones equipped with high-resolution multispectral cameras and thermal sensors, this system collects detailed visual and spectral data of crops, which are then processed using machine learning algorithms to assess ripeness and detect spoilage. This automated approach offers real-time insights that can help farmers make timely decisions regarding harvesting, thereby reducing food waste, improving produce quality, and optimizing labor use.

Agriculture plays a critical role in feeding the world's growing population, with the quality and freshness of produce being key factors for both consumer health and market success. However, traditional methods of monitoring crop health and quality often rely on manual labor, which can be inefficient, labor-intensive, and prone to human error. To address these challenges,technological innovations are being integrated intofarming

agriculture faces increasing pressure to meet the demands of a growing global population, the integration of such innovative technologies is essential for driving future advancements in crop production and sustainability.

In addition to improving crop quality, the project also aims to address critical challenges related to environmental sustainability and economic viability. The use of drones minimizes the need for ground vehicles and human intervention, reducing the environmental impact associated with traditional farming methods. Additionally, by optimizing harvest times and reducing spoilage, farmers can achieve higher yields with lower input costs, ultimately contributing to a more sustainable and profitable agricultural industry.

II. OBJECTIVES

The primary goal of this project is to develop an autonomous drone-based system that leverages high-resolution multispectral cameras and thermal sensors for assessing the freshness of agricultural produce. By employing advanced machine learning algorithms to analyze captured visual and spectral data, the system aims to accurately identify indicators of crop ripeness and spoilage in real time. This innovative approach is designed to automate the monitoring process, providing farmers with timely insights that facilitate informed decisions regarding harvest and distribution.

Ultimately, the project seeks to enhance the overall quality of yield, minimize waste, and improve labor efficiency, thus addressing the increasing demand for high-quality agricultural products. Furthermore, the system will be optimized for various crop types and tailored to different farming environments, ensuring scalability and adaptability. Key considerations will include regulatory compliance, data security, and the environmental impact of drone operations, all of which will be integral to the successful implementation of this technology in modern farm management practices

III. HARDWARE REQUIREMENTS:

Drone Model: similar drone with GPS capabilities. Camera: High-resolution (12 MP or higher) camera for image and video capture.
Flight Controller: Capable of autonomous navigation (e.g., PX4, DJI SDK).
GPS Module: For accurate drone positioning. Battery: High-capacity rechargeable battery for extended flight time (minimum 30 minutes).
Processing Unit: Onboard computer or edge device for real-time processing

Computer/Server for Image Processing: CPU: Intel Core i7 or higher.

GPU: NVIDIA GPU with at least 4GB VRAM for real-time inference (e.g., GTX 1650, RTX 3060).

RAM: 16 GB or higher.

Storage: 500 GB SSD for data storage and model storage.

IV. SOFTWARE REQUIREMENTS:

Operating System: Windows 10/11 or Linux (Ubuntu 20.04 or higher).

Drone Control Software:DJI SDK or PX4 for autonomous navigation.

AI/ML Frameworks: TensorFlow or PyTorch for YOLO model training.OpenCV for image processing and video feed handling.YOLO (You Only Look Once) for object detection and freshness classification.

Development Tools: Python for AI model development and drone control programming.

V. EXISTING SYSTEM

In Existing Sysrtem an efficient method for vegetable and fruit freshness detection is implemented using deep features extracted from pre- trained deep learning models of different architectures. The image sizes of fresh and rotten vegetables and fruits are reset, and the deep features representing their freshness are extracted by deep learning models with various architectures. These deep features are then fused, and the high-dimensional deep feature space is reduced to a low- dimensional feature space using PCA (Principal Component Analysis). The freshness of vegetables and fruits is subsequently detected through machine learning methods.

The experimental results show that the combination of deep features extracted from three pre-trained deep learning models—GoogLeNet, DenseNet-201, and ResNeXt-101—along with PCA dimensionality reduction, achieves the highest accuracy rate of 96.98% for vegetable and fruit freshness detection.

VI. PROPOSED SYSTEM

In this current project, we will implement OpenCV for image processing to improve real-time analysis and integrate it with our existing framework. By combining the strengths of deep learning models and OpenCV, we aim to provide a robust and scalable solution for monitoring the freshness of vegetables and fruits on farms. This implementation not only enhances detection accuracy but also further reduces the need for manual labor, thereby streamlining the entire monitoring process.This introduction lays the foundation for the development and implementation of an innovative, technology-driven solution aimed at optimizing agricultural practices. By addressing key challenges and leveraging cutting-edge technology, this project aims to revolutionize the way farmers monitor and maintain the quality of their produce while reducing labor dependency.

VII. SYSTEM ARCHITECTURE

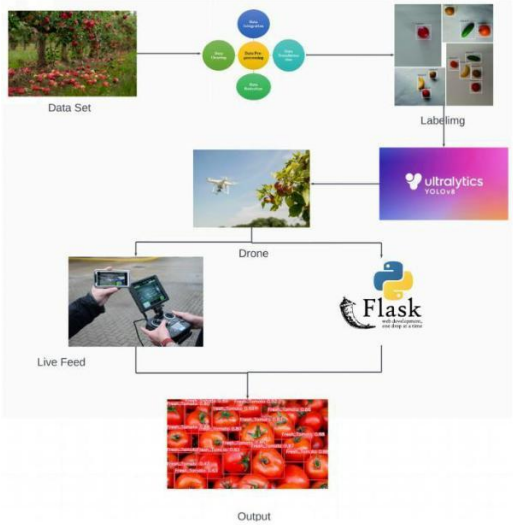

FIGURE 1

The architecture diagram for this project outlines the seamless integration of **drone technology** with advanced **image processing** and **machine learning algorithms** to monitor the freshness of agricultural produce in real-time. The system is composed of several key components: drones equipped with **multispectral cameras** and **thermal sensors** capture real-time data from farm fields. This data is processed through an **image processing module**

powered by **OpenCV**, which analyzes the captured images and prepares them for classification. A pre-trained **machine learning model** then classifies the produce based on its freshness.

VIII. MODULES

DRONE DATA ACQUISITION

A commercially available drone equipped with high- resolution cameras and integrated with an ESP-32 microcontroller for IoT-based communication.

The drone is programmed using GPS-based navigation and obstacle avoidance algorithms to autonomously survey agricultural fields and storage areas. Techniques such as A* or similar path- planning algorithms are employed for efficient movement.

The drone collects high-resolution images and videos of fruits and vegetables in real-time from multiple angles. This aerial view ensures comprehensive coverage, even in large-scale fields.

IMAGE PREPROCESSING

Captured images are preprocessed to improve model accuracy, including Standardizing image dim ensions for model input.

Scaling pixel values to enhance feature detection. Applying transformations such as rotation, flipping, and cropping to increase dataset variability.

DEEP LEARNING MODEL

The system uses the YOLO (You Only Look Once) deep learning model for object detection and classification. A custom dataset containing images of fresh and rotten fruits and vegetables is used to train the model. The dataset is categorized into 20 classes across the Fruits and Vegetables directories, including items like fresh apples, rotten tomatoes, etc.

YOLO processes the drone-captured images and videos to detect and classify produce with high accuracy and speed. The model outputs bounding boxes around detected objects along with their freshness labels.

REAL-TIME VIDEO PROCESSING

Live Feed Analysis: The drone streams video in real-time, which is processed frame-by-frame using OpenCV.

The YOLO model classifies each frame, providing instant feedback on the freshness of produce. Results are displayed on a user interface.

IOT INTEGRATION FOR COMMUNICATION

The drone-mounted ESP-32 microcontroller enables wireless communication, transmitting detection results to a ground station or cloud server.

This setup allows remote monitoring and control of the drone.

SCALABILITY AND FIELD DEPLOYMENT

The drone-based system can cover large agricultural fields, enabling scalability for farmers and agri-businesses. The lightweight nature of YOLO ensures real-time performance without significant hardware limitations.Efficiently monitors large fields with minimal human intervention.

Captures images from angles and locations inaccessible to ground-based systems. Reduces the ime required for manual inspection, ensuring timely action to prevent spoilage.

\

IX. RESULT AND DISCUSSIONS:

This project offers an innovative solution to a critical agricultural challenge: monitoring the freshness and quality of produce. By leveraging **drone technology** equipped with **multispectral cameras** and integrating advanced **image processing techniques**, the system effectively addresses key issues in farm management. The proposed use of **machine learning algorithms** to analyze real-time data enables more efficient decision-making regarding harvesting and distribution.

a. OUTPUT

FIGURE 2

The existing approach, which employs deep features from pre-trained deep learning models for freshness detection, has already demonstrated high accuracy. However, the integration of **OpenCV** in the proposed system enhances real-time analysis capabilities while minimizing manual intervention, thereby improving scalability and usability. This innovation can significantly reduce labor costs, enhance yield quality, and minimize waste by providing precise insights into crop ripeness and spoilage.

The technical feasibility of this solution is supported by the widespread adoption of drones in agriculture, though challenges such as farmers' willingness to adopt the technology and the need for regulatory compliance remain. These barriers could be mitigated through educational initiatives and scalable deployment strategies tailored to various agricultural settings.

b. F1-CONFIDENCE CURVE ANALYSIS

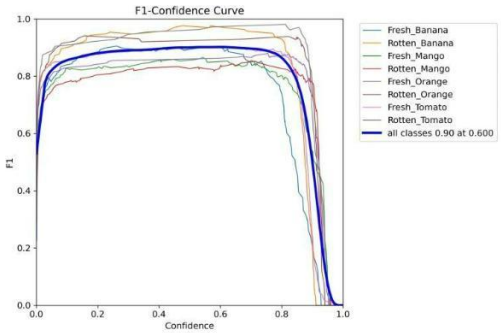

FIGURE 3

The F1-Confidence Curve presented in Figure X illustrates the model's performance in classifying fresh and rotten fruits with varying confidence thresholds. The F1-score, a harmonic mean of precision and recall, is plotted against confidence levels to assess the trade-off between precision and recall at different thresholds.Each curve corresponds to a specific fruit category (e.g., Fresh_Banana, Rotten_Tomato), showing how the model's confidence affects classification accuracy. The thick blue line represents the overall F1-score across all classes, achieving a peak value of 0.90 at a confidence threshold of 0.600. This indicates that at 60% confidence, the model achieves optimal precision-recall balance for detecting freshness.

c. PRECISION -CONFIDENCE CURVE ANALYSIS

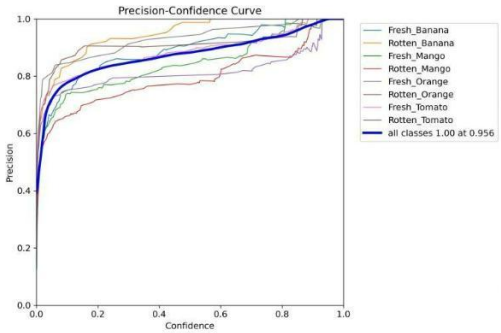

FIGURE 4

The Precision-Confidence Curve in Figure X illustrates the relationship between model confidence and precision for classifying fresh and rotten fruits. Precision measures the proportion of correctly classified positive instances out of all predicted positive instances, making it crucial for assessing the model's ability to minimize false positives. Each curve represents a specific fruit category, showing how precision improves as confidence increases. The thick blue line represents the overall precision across all classes, reaching a maximum value of 1.00 at a confidence threshold of 0.956. This suggests that at high confidence levels, the model achieves perfect precision, but at the cost of reduced recall.

d. PRECISION-RECALL CURVE ANALYSIS

The Precision-Recall (PR) Curve in Figure X illustrates the model's ability to balance precision and recall for each fruit class. It is particularly useful for imbalanced datasets where accurate classification of fresh and rotten produce is essential. Each curve represents a specific category, while the thick blue line shows overall model performance, achieving a mean average precision (mAP) of 0.947 at IoU=0.5.

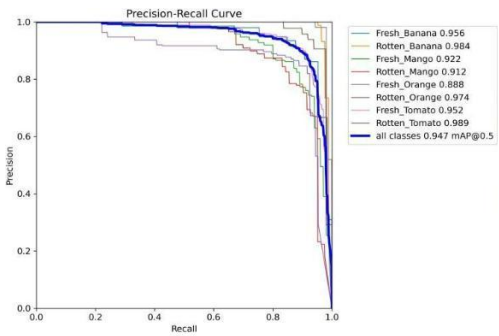

FIGURE 5

The graph indicates that most classes maintain precision above 0.9 until recall surpasses 0.8, after which some decline is observed. This suggests the model effectively detects fresh and rotten fruits with minimal false positives. Notably, rotten banana and rotten tomato achieve the highest precision (0.984 and 0.989), highlighting strong detection capabilities for these categories.

e. RESULTS

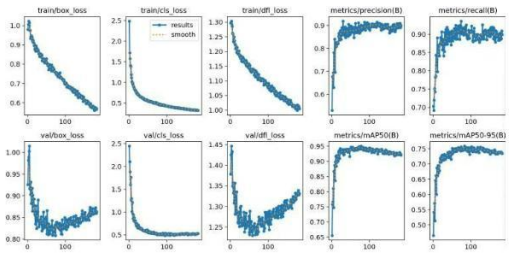

FIGURE 6

The training performance of the YOLO-based fruit classification model was evaluated using key metrics, as shown in Figure X. The training losses, including box loss, classification loss, and DFL loss, steadily decreased over epochs, indicating effective learning and proper model optimization without overfitting. The validation losses initially declined but showed slight fluctuations in later epochs, suggesting potential dataset complexity or fine- tuning adjustments. Performance metrics such as precision and recall improved over time, stabilizing above 0.9, demonstrating the model's reliability in detecting and classifying fruits. Additionally, the mean average precision (mAP50 and mAP50-95) reached values between 0.75 and 0.95, confirming strong object detection capabilities. These results validate the effectiveness of the Fresh Sense framework for fruit quality monitoring using autonomous drones, with future improvements focusing on dataset augmentation and real-world deployment.

X. CONCLUSION

The integration of drone technology with machine learning and image processing offers a promising approach to modernizing agriculture. This system has the potential to transform how farmers monitor produce quality, providing real-time insights that could lead to more informed decisions and better management practices. With its potential to reduce labor costs, improve crop yield, and minimize waste, the project addresses several critical challenges in agriculture today. Further validation and optimization are necessary to ensure the system's effectiveness across different crop types and farming environments. Overall, this technology-driven approach could revolutionize produce quality monitoring, enhancing sustainability and efficiency in the agricultural sector

***Abstract* - The use of deep learning techniques for classifying neurological brain disorders marks a major breakthrough in research, with significant implications for improving diagnosis and treatment approaches. By employing convolutional neural networks (CNNs), we developed a robust framework capable of precisely identifying various neurological conditions using medical imaging modalities such as MRI and CT scans. Our approach integrates multi-modal data, combining structural, functional, and diffusion-weighted imaging to deliver a comprehensive analysis of brain structure and connectivity. Rigorous testing and validation on extensive datasets demonstrate that our model achieves exceptional accuracy in distinguishing conditions like Alzheimer's disease, Parkinson's disease, multiple sclerosis, and epilepsy. Moreover, interpretability tools, such as attention mechanisms, shed light on the key features driving classification decisions, offering valuable insights into the underlying pathological processes. These findings not only deepen our understanding of neurological disorders but also contribute to the development of advanced diagnostic systems and tailored therapeutic solutions, ultimately enhancing patient care and quality of life.**

Keywords – Neurological Brain Disorder, Convolution Neural Network, Pathological, Brain Disorder's Disease.

I. Introduction

Brain Disorder's disease is a degenerative neurological disorder characterized by the gradual shrinking of the brain (atrophy) and the loss of brain cells. It is the primary cause of dementia, which involves a progressive deterioration in cognitive, behavioral, and social skills, eventually affecting an individual's ability to live independently. Initial symptoms typically include challenges in recalling recent events or conversations. As the condition worsens, individuals suffer from severe memory deficits and become unable to perform daily activities. Although medications can offer temporary relief or slow the progression of symptoms, these interventions help patients retain functionality and independence for a limited time.

[2][4] Additionally,specialized programs and support services provide valuable assistance to both patients and caregivers. At present, no cure or treatment exists to reverse Brain Disorder's disease or stop its progression in the brain. In advanced stages, complications stemming from significant brain function loss, such as dehydration, malnutrition, or infections, are often fatal. Neurological brain disorders, such as Alzheimer's disease, Parkinson's disease, multiple sclerosis, and epilepsy, present complex medical challenges with significant impacts on patients' overall well-being. Achieving timely and accurate diagnoses is crucial for proper management and effective treatment strategies. However, traditional diagnostic methods, which predominantly depend on clinical evaluations and imaging techniques, can be time-intensive, subjective, and prone to variability among medical practitioners. Advancements in artificial intelligence (AI), particularly deep learning, offer innovative solutions to overcome these challenges by providing automated, efficient, and highly accurate diagnostic tools.[9] Deep learning, a specialized subset of AI, has revolutionized convolutional neural networks (CNNs) have demonstrated exceptional efficacy in analysing medical imaging data, including MRI, CT, and PET scans, to detect and classify these conditions. These cutting-edge techniques facilitate precise recognition and early detection, which are vital for timely and effective interventions. This study explores the application of deep learning techniques in classifying neurological brain disorders, focusing on integrating multi-modal data to improve diagnostic accuracy. By utilizing structural, functional, and diffusion imaging modalities, these models provide a comprehensive view of brain structure and connectivity. Additionally, interpretability approaches, such as attention mechanisms, help identify critical features influencing classification outcomes, offering deeper insights into the pathological mechanisms of these disorders. The goal of this research is to demonstrate how deep learning enhances the accuracy and reliability of neurological disorder classifications while enabling the development of personalized medical approaches. The adoption of AI- powered solutions within healthcare systems has tremendous potential to enhance patient outcomes, optimize treatment protocols, and reduce the burden on healthcare providers.

II. Literature Survey

In paper [1] Numerous investigations have focused on examining features linked to brain state trajectories, which are subsequently utilized for training interpretable classifiers. However, the combination of explainable dFNC classifiers followed by clustering methods remains underexplored.

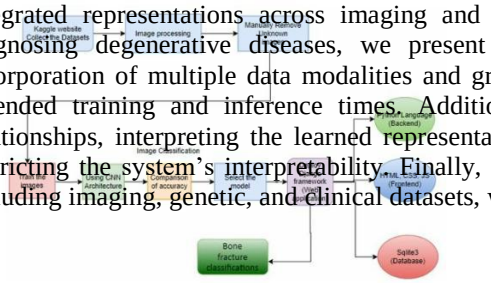
In paper [2] demonstrates how to identify distinct dFNC states. Additionally, we introduce novel metrics to evaluate classifier explanations, offering deeper insights into SZ's impact on brain network dynamics. Our results suggest that schizophrenia being temporally constrained. Beyond revealing SZ's impact on brain network dynamics, this method holds promise for investigating a broad spectrum of neurological and neuropsychiatric conditions in future dFNC studies.

In paper [3] Machine learning (ML), a subfield of artificial intelligence, enables systems to perform tasks autonomously without explicit programming. ML is increasingly being used for diagnosing and predicting brain disorders, with significant advancements in this field. Recent advances in ML have evolved from simple classification of diseases against control groups to more complex differential diagnosis techniques. There has been a noticeable rise in research dedicated to forecasting future patient states. While earlier studies predominantly relied on neuroimaging data, the current focus is on integrating multimodal datasets.

In Paper [4] Although dementia remains the primary focus, methods are now being developed for a growing number of neurological and psychiatric disorders. ML holds substantial promise for aiding both the diagnosis and prognosis of brain disorders. However, challenges persist, including the need for standardized validation processes, more extensive generalization studies, and the development of interpretable models to address the limitations of opaque "black-box" systems.

In paper [5] Deep learning has transformed the field of machine learning and computer vision, enabling systems to solve previously impossible problems. Today, deep learning is extensively used in areas such as natural language processing, image classification, medical diagnostics, handwriting recognition, facial recognition, speech recognition, and biometrics. This paper offers a comprehensive review of deep learning techniques applied to the diagnosis of brain disorders. It highlights the critical role deep learning plays in automating medical diagnostics for conditions such as brain tumors, Alzheimer's, Mild Cognitive Impairment, brain hemorrhages, and Parkinson's disease. The paper also explores recent advancements in deep learning techniques and discusses the future potential of deep learning in diagnosing brain disorders.

In paper [6] Current research on diagnostic models generally focuses either on improving model performance or ovisualizing and interpreting trained models. We introduce a new "learn-explain-reinforce" (LEAR) framework that integrates diagnostic model training, visual explanation generation, and model reinforcement based on these explanations. To generate visual explanations, we create counterfactual maps, which demonstrate how modifications to input data could result in different classifications. For instance, a counterfactual map might identify potential abnormalities in a normal brain image that would lead to an Alzheimer's diagnosis.



In paper [8] counterfactual maps offer valuable, data-driven insights for AD diagnosis using structural MRI and can be leveraged to enhance model generalization. We developed an attention-based feature refinement module that uses these maps to guide model learning. The explanation and reinforcement components work together iteratively to refine the model. Our method was validated through both qualitative and quantitative assessments .

In paper [9] a progressive neurodegenerative disorder, has been linked to single nucleotide polymorphisms (SNPs) as potential biomarkers for accurate diagnosis. This study aims to identify SNP biomarkers associated with AD and perform reliable classification. In contrast to earlier studies, we employ deep transfer learning combined with extensive experimental analysis for AD classification. Initially, convolutional neural networks (CNNs) were trained on genome-wide association studies (GWAS) data from the AD Neuroimaging Initiative, followed by further refinement using deep transfer learning with an additional AD GWAS dataset. The final set of features was then used for AD classification with a Support Vector Machine (SVM). Our experimental results demonstrated an accuracy of 89%, a significant improvement over previous method.

In paper [10] affects millions of individuals globally, with its characteristic symptoms emerging after the accumulation of amyloid-beta and tau proteins. Identifying early biomarkers for AD is essential for developing therapies capable of altering disease progression. To investigate DNA methylation as a potential blood-based biomarker for AD, we analyzed a cohort of 653 individuals from the Alzheimer's Disease Neuroimaging Initiative (ADNI), which included individuals diagnosed with AD, mild cognitive impairment (MCI), and age-matched healthy controls. The analysis incorporated extensive multi-omics and clinical data, advancing our understanding of AD pathology and supporting the discovery of biomarkers for early diagnosis.

III. Existing System

Graph learning methods have made significant strides in disease diagnosis by adeptly modeling unstructured data, such as relationships between subjects. While the role of imaging, genetic, and clinical data in diagnosing degenerative diseases is well-established, current approaches often struggle to fully capitalize on the interconnections between these modalities. The challenge of effectively combining and leveraging information from these varied data sources remains a substantial hurdle. This study introduces a novel graph-based fusion (GBF) framework designed to address this issue. To extract relevant imaging-genetic features, we propose an imaging-genetic fusion module that uses an attention mechanism to create both modality-specific and integrated representations across imaging and genetic data. Additionally, recognizing the importance of clinical data in diagnosing degenerative diseases, we present a multi-graph fusion module. However, several challenges persist. The incorporation of multiple data modalities and graph-based fusion strategies may introduce computational burdens, leading to extended training and inference times. Additionally, while graph learning techniques are effective in capturing complex relationships, interpreting the learned representations and understanding their clinical relevance remains difficult, potentially restricting the system's interpretability. Finally, the system's efficacy heavily depends on the quality and availability of data, including imaging, genetic, and clinical datasets, which can vary significantly across different datasets and institutions.

IV. Proposed System

We developed a system aimed at building a project utilizing deep learning techniques. In recent years, deep learning and artificial intelligence have significantly impacted various industries, driving innovation and improvements. In this context, we sought to apply deep learning approaches to diagnose brain disorders. We compiled historical data from patients, including records of individuals with brain disorders, those without the condition, and those exhibiting related symptoms. By processing this data, our machine learning model works to identify patterns within the datasets through sophisticated calculations. After recognizing patterns in images using various deep learning techniques, the system is able to predict new cases based on historical data. When an image from a patient is input, the algorithm evaluates whether the individual is affected by the disorder. We developed a robust application ready for deployment and built a predictive model using deep learning. We implemented cutting-edge neural network architectures and compared multiple models to achieve the best possible accuracy and performance.

V. ARCHITECTURE

a. System Architecture

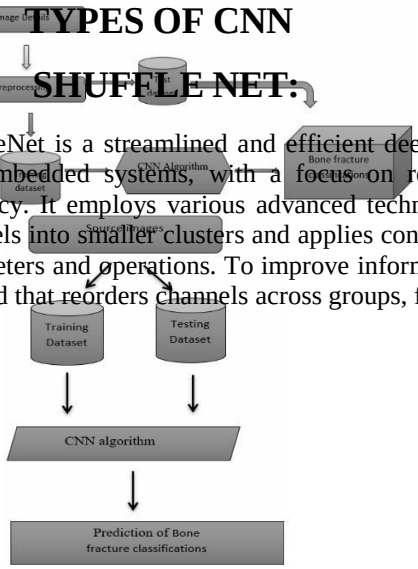
Fig 1 Architecture

Data Preparation and Model Training (CNN): The dataset is processed, including steps like reshaping, resizing, and converting the images into array format. The same processing is performed on the test image. The dataset contains around 10 different bone fracture types, from which any image can be chosen as a test sample for the system. The model (CNN) is trained using the training dataset, allowing it to detect and categorize the test image based on the associated condition. The CNN architecture includes layers such as Dense, Dropout, Activation, Flatten, Convolution2D, and MaxPooling2D. After successful training, the software can categorize bone fracture images using the trained model. Once preprocessing and training are completed, the system compares the test image with the trained model to predict the correct bone fracture classification.

VI. TYPES OF CNN

i. SHUFFLE NET:

ShuffleNet is a streamlined and efficient deep convolutional neural network architecture, mainly designed for mobile devices and embedded systems, with a focus on reducing computational load and memory consumption while maintaining high accuracy. It employs various advanced techniques to achieve this goal, starting with group convolution, which divides input channels into smaller clusters and applies convolutions to each cluster separately, thereby significantly decreasing the number of parameters and operations. To improve information exchange between these separate groups, ShuffleNet uses channel shuffle, a method that reorders channels across groups, facilitating better communication and data mixing.



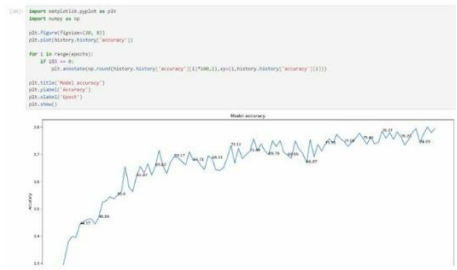


Fig 2 Architecture

Additionally, the model incorporates pointwise group convolution (1x1 convolutions), which further minimizes computational demands by performing group convolutions instead of dense convolutions after depthwise convolutions. Depthwise convolution itself divides traditional convolution into two stages—depthwise (spatial) and pointwise (1x1)— which reduces the number of parameters and floating-point operations.

Fig 3 Workflow

The architecture also reduces the number of channels before group convolution and increases them afterward, helping the network maintain a low computational cost while retaining sufficient capacity. For downsampling, stride 2 is used in specific layers to reduce the spatial resolution, which helps in lowering computational effort as the network grows deeper. ShuffleNet is offered in two versions: ShuffleNet 1.0, which uses fewer groups and balances speed and accuracy, and ShuffleNet 2.0, an optimized version that improves both the efficiency and accuracy of group convolutions and channel shuffling..

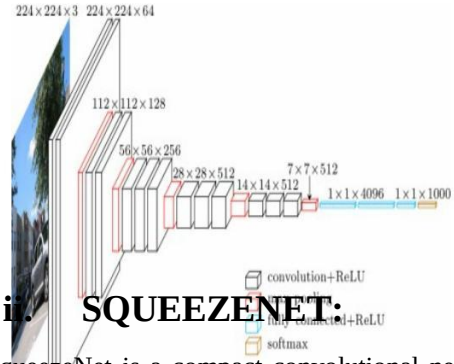

Fig 4 Shuffle Net

ii. SQUEEZENET:

SqueezeNet is a compact convolutional neural network (CNN) architecture designed to optimize image classification tasks with minimal computational overhead. Developed by researchers at DeepScale, UC Berkeley, and Stanford in 2016, its primary objective is to deliver comparable performance to larger models like AlexNet while significantly reducing the number of parameters. The innovative element in SqueezeNet is the introduction of This strategy leads to a drastic reduction in the model's parameter count while preserving high accuracy The architecture of SqueezeNet incorporates the "squeeze" operation, which reduces the dimensionality of input channels using 1x1 convolutions, and the "expand" operation, which amplifies the network's representational capacity using both 1x1 and 3x3 convolutions. This approach allows SqueezeNet to achieve a substantial reduction in model size, typically requiring fewer than 50 times the number of parameters compared to conventional CNNs like AlexNet, without compromising accuracy. Furthermore, SqueezeNet integrates techniques such as late down sampling, which preserves spatial information longer, and model compression strategies like pruning and weight sharing, further optimizing its efficiency. Thanks to its small footprint and high efficiency, Squeeze Net is particularly advantageous for scenarios where memory and computational power are constrained, such as edge computing and Internet of Things (IoT) applications. Despite its compact size, Squeeze Net performs on par with larger models in image classification tasks, making it an ideal choice for deploying deep learning models in environments with limited resources. Its ability to balance accuracy with efficiency has led to its adoption in diverse applications, ranging from real-time image recognition to autonomous systems.

CONCLUSION

In conclusion, of neurological brain disorders has demonstrated considerable promise in enhancing diagnostic accuracy and improving treatment outcomes. Through the adoption of advanced algorithms like researchers have significantly improved their ability to identify subtle patterns and irregularities in complex brain imaging data. These advancements not only contribute to the early detection and better understanding, but also pave the way for developing personalized treatment approaches tailored to each patient's unique characteristics. Nonetheless, despite these promising strides, continued research and improvement are essential to address ongoing challenges, such as the need for larger, more diverse datasets and the incorporation of various data modalities. As deep learning technologies continue to evolve, their integration into clinical practices providing more precise diagnostics and ultimately improving patient outcomes.

VII. FUTURE SCOPE

For future research, combining sophisticated deep learning methods with neuroimaging data could improve the precision of classifying neurological brain disorders. Broadening the scope to include multi-modal data and integrating longitudinal studies could further enhance diagnostic accuracy and tailor treatment strategies. In forthcoming studies, the integration of advanced deep learning techniques with neuroimaging data has the potential to substantially enhance the precision in classifying neurological brain disorders. Expanding the scope to include multi-source datasets and incorporating longitudinal research could further improve diagnostic accuracy and enable more tailored therapeutic approaches. Additionally, leveraging real-time data from wearable devices and mobile health technologies could facilitate continuous monitoring, offering more real- time insights into the progression of diseases. Investigating the use of transfer learning to adjust models across different demographic groups or imaging techniques may also contribute to increased model adaptability. Moreover, developing interpretable AI models will be critical to ensure that the predictions made by these systems are transparent and practically applicable in clinical environments. Finally, working closely with healthcare providers and medical experts will be essential to ensure that these deep learning models are seamlessly implemented into practical healthcare workflows, delivering acionable insights that can directly benefit patient treatment and care.

Abstract. Our project Virtual Encyclopedia with Augmented Reality (AR) is a pioneering learning platform that improves education by combining immersive, interactive experiences into conventional knowledge assets. In contrast with traditional encyclopedias based on static text and imagery, this system takes advantage of AR technology for delivering real-time three-dimensional visualizations, animations, and interactive simulations, making abstract concepts more attractive and accessible. This project will help to close the gap between experiential learning and theoretical learning by allowing users to explore historical artifacts, scientific models, and engineering structures in an interactive manner. The adaptive learning method guarantees customized content delivery according to user interaction, enhancing knowledge retention and addressing different learning styles.Mobile technology and cloud-based infrastructure enable this Virtual Encyclopedia to democratize access to quality education, making it possible for students in disadvantaged and remote locations to enjoy the same interactive learning as students in well-endowed institutions. The platform enables teachers to continuously update and enrich material, ensuring that the content is current and in line with new findings and innovations. Through AR-based education, this initiative drastically increases student interaction, stimulates curiosity, and supports lifelong learning. By revolutionizing conventional learning approaches, our system opens doors to a more participatory, open, and accessible future of e-learning.

Keywords. Interactive Learning, Educational Technology, Immersive Learning, 3D Visualization, Adaptive Learning, Digital Education, Knowledge Retention, Cloud-Based Learning

1. INTRODUCTION

The quick development in technology has revolutionized the conventional learning processes, and education has become more interactive, engaging, and accessible. The Virtual Encyclopedia based on Augmented Reality (AR) is intended to change the means of accessing and comprehending knowledge by incorporating AR technology into an interactive learning platform. As opposed to traditional encyclopedias, which are based largely on static text and images, this system supports understanding by enabling users to interact with three-dimensional (3D) models, animations, and simulations that illustrate concepts. This new method assists students in comprehending intricate scientific concepts, historical events, and engineering principles more effectively in a more engaging and immersive way.This project seeks to close the gap between theoretical learning and real-world application by creating an AR-enriched learning environment that can be accessed using mobile devices and AR-enabled platforms. The system aims to serve a wide variety of learners, providing universal access to quality education, particularly for learners in underprivileged and distant regions. Based on a cloud-based system, the platform provides real-time update of content, and thus allows educators to include the latest science, history, and technology breakthroughs in the educational content. Also, employing adaptive learning methodologies personalizes the learning experience through user interaction, hence enhancing engagement and knowledge retention.The use of Augmented Reality in this project augments experiential learning, increasing education's interactivity, inclusivity, and efficacy. The Virtual Encyclopedia is not merely a strong aid for students but also an useful tool for instructors who wish to bring their own teaching practices up to date. This paper investigates the importance of AR-based learning, outlines the system architecture and deployment, and describes the influence of AR-enabled learning on the participation of learners and their performances.

2. RELEVANT RESEARCH

The use of Augmented Reality (AR) in education has transformed learning as it makes subjects such as science, mathematics, and history more engaging and immersive. Different studies on the subject show the power of AR to enhance student interest, retention of knowledge, and conceptualization of subjects in different disciplines. Such an AR-based educational platform is Devar AR Anatomy, founded in 2015, which makes medical education stronger as it facilitates students to interact with 3D models of human anatomy. Unlike traditional textbooks and cadaveric learning, this technology enables a real-time, hands-on experience, and students can rotate, dissect, and explore human organs in 3D space. Studies have established that interactive learning of such a nature has better spatial knowledge and higher rates of retention.

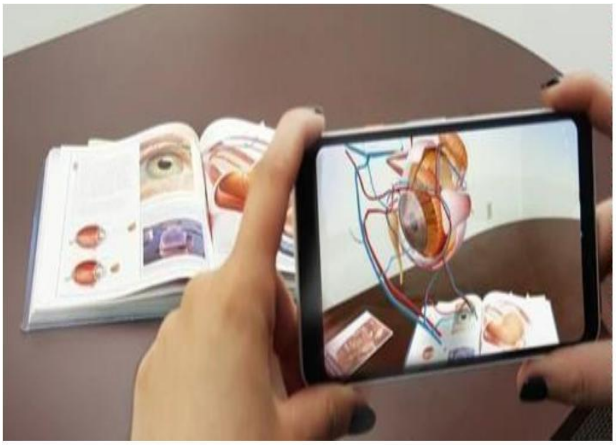

Fig.1

Furthermore, a study by Cheng & Tsai (2021) illustrated how AR-based simulations enhance conceptual understanding in science education by simplifying abstract theories. Similarly, Wu et al. (2020) explored the use of AR-based virtual laboratories, which are a potential alternative to actual experiments, especially for schools with inadequate laboratory equipment. Other advancements, such as those of Almalki & Alshahrani (2023), focus on integrating AR with AI to create adaptive, customized learning environments in which material adjusts according to students' progress and levels of comprehension. These researches offer a solid basis for the Virtual Encyclopedia with AR, which will provide an interactive learning environment where students can learn different topics in AR-enhanced 3D visualizations, making it easier to generalize theoretical knowledge into real-world experiences. Through leveraging these research outputs, the Virtual Encyclopedia project hopes to make learning more interactive, accessible, and effective for various types of learners and learners from various fields of study.

3. PROPOSED SYSTEM

The Augmented Reality (AR) Virtual Encyclopedia is intended to recreate digital learning into an engaging, interactive learning experience with enhanced knowledge retention and engagement. Traditional learning procedures rely on textbooks and static pictures, which do not have the power to capture students' attention. The system at hand utilises AR technology to present information in the form of 3D, interactive objects so that learners are able to visualise complex concepts more vividly. Through the use of mobile phones, AR headsets, or smart glasses, learners are able to engage with virtual objects, ancient artifacts, scientific models, and animated explanations to better understand a range of topics. The platform has several modules, such as content visualization, speech recognition for interactive questions,cloud storage for easy access to AR materials, and AI-powered personalized learning tracks. Unlike traditional learning platforms, the Virtual Encyclopedia is able to adjust content in accordance with user preferences, progress, and engagement levels, making it a personalized and adaptive learning experience. Moreover, it allows for multi- user collaboration, where students and teachers can explore AR models together in real-time.

This new methodology fills the gap between theoretical knowledge and practical application, making learning more accessible, interesting, and efficient for various educational disciplines like science, history, geography, and medicine

4. TECHNIQUE

Virtual Encyclopedia with Augmented Reality (AR) makes use of a mixture of innovative technologies and methods for the purpose of building an immersive and interactive learning space. The main method is by visualization with the aid of Augmented Reality, whereby 3D models, animations, and interactive simulations are projected onto the real world with the use of AR frameworks like ARKit, ARCore, and Vuforia. Through this, learners are able to study subjects such as science, history, and medicine practically, enhancing conceptual comprehension and recall. Another prominent method is Artificial Intelligence (AI)-based personalization, in which machine learning algorithms process user interactions and learning behaviors to suggest personalized learning material. This ensures that students get adaptive learning experiences based on their pace and comprehension. Furthermore, voice-based questioning is supported by Natural Language Processing (NLP) and speech recognition, and the virtual encyclopedia may be controlled with verbal instructions by users for an experience more similar to that of humans. To ensure accessibility and scalability, database management practices and cloud computing are employed, ensuring seamless content storage, retrieval, and live updation. Multi-platform compatibility approaches are included to facilitate the support of multiple devices like smartphones, tablets, AR headsets, and smart glasses so that the system can be made accessible over a wide platform. Lastly,cooperative learningmethods are implemented to enable simultaneous shared access by different users of the same AR content, which enables group discussion as well as collaboration. Through integrating these methods, the Virtual Encyclopedia offers an extremely interactive, engaging, and personalized learning experience which increases student participation, accessibility, and final learning achievement.

5. SYSTEM ARCHITECTURE

The system architecture of the AR Learning Environment is created to support an immersive, personalized, and interactive learning experience. It starts with the User Interaction Layer, in which the users engage via AR-capable devices such as smartphones and tablets. The devices are the vehicle for viewing augmented reality content and giving voice commands. The Application Layer is the centerpiece of the system, which utilizes the AR Engine (ARKit/ARCore) to project 3D learning material, an AI recommendation system to read user activity and offer personalized recommendations, and NLP & voice recognition capabilities to interpret voice inputs and enable voice-free interaction.

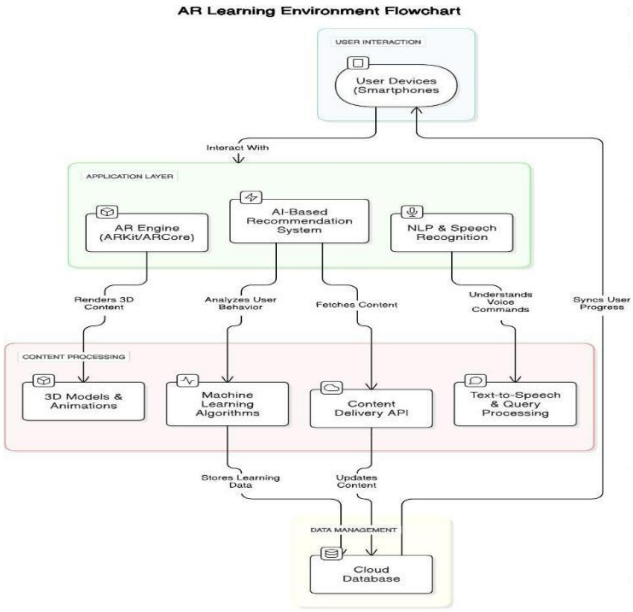

Fig. 2. Flowchart

The Content Processing Layer enables these functionalities through content creation and management of learning material. It contains 3D objects and animations for graphical learning, machine learning logic for studying the users' preference patterns and mapping optimal learning sequences, content delivery APIs for retrieval of suitable content, and text-to-speech/query processing for sound learning scenarios. The Data Management Layer provides smooth integration and synchronization through the storage of user data and learning progress within a cloud database, allowing constant updates and availabilityof content on anydevice. This end-to-end architecture guarantees a dynamic and accessible learning platform customized to specific user requirements, promoting engagement, knowledge retention, and lifelong learning

6. MODULES

The Augmented Reality (AR) Virtual Encyclopedia consists of a number of important modules that collaborate to offer a new and engaging learning experience. The User Interface Module provides an interactive interface for students and teachers, allowing navigation of content, tracking of personalized progress, and AR-driven interactions. The AR Content Module creates and renders dynamic 3D models and animations through AR platforms such as ARKit and ARCore. A Content Management System (CMS) enables administrators to upload, modify, and maintain learning content in an efficient manner, coupled with a cloud database for painless storage and recall. The Recommendation Engine Module applies machine learning to acquire user behavior and provide personalized recommendations, improving engagement. A Natural Language Processing (NLP) Module supports voice interaction using speech recognition and text-to-speech capabilities for accessibility. The Backend Services Module offers secure communication through API gateways, manages user login, and services databases for tracking preferences and progress. The module also consists of a Data Analytics Module for tracking user interaction and system usage, giving educators valuable intelligence. Finally, the Cloud Management Module ensures scalability and reliability through the utilization of cloud infrastructure, e.g., a Content Delivery Network (CDN) to deliver content in an optimal way and synchronize in real-time. All these modules together create a strong platform that revolutionizes learning with AR.

7. DISCUSSION

The Augmented Reality Virtual Encyclopedia revolutionizes learning by providing interactive and immersive learning experiences. It simplifies learning through 3D visualizations, enhances engagement, and allows personalized learning through AI- based recommendations. The platform uses cloud infrastructure for scalability and accessibility and provides teachers with information about student performance through data analytics. Despite challenges like device compatibility and data privacy, this platform has great potential to bridge learning gaps, foster curiosity, and enable lifelong learning.

8. FUTURE WORK

Future implementation of a virtual encyclopedia based on augmented reality (AR) presents promising opportunities for education and interaction. Increasing the scope of the content to include more subjects and enabling collaborative content creation can increase the platform's versatility and dynamism. Increasing AR features, including markerless AR, gesture, and voice control, and supporting multi-user experiences can make learning environments more immersive and interactive. Integration of machine learning and AI is possible to drive personalized learning processes, natural language processing for speech-based interactions, and visual perception to recognize actual-world objects. Gamification in the form of AR-based quiz games, AR-based interactive tours, and social networking can popularize learning. Future work can also include cross-platform compatibility with wearables, VR, and mixed reality devices, alongside expanding accessibility with offline features and localization. Advanced data visualizations and interactive timelines/maps can be integrated, and content verification through blockchain could ensure integrity. Ultimately, the future work in this project aims to deepen user engagement through richer, more interactive, and customizable educational experiences.

9.RESULT

The outcome of the Virtual Encyclopedia with Augmented Reality project proves improved learning performance and user engagement. The AR platform increased knowledge retention and comprehension of complicated ideas through interactive 3D models and real-time overlays of content. Feedback from users reflected improved motivation and interest, especially in topics dealing with visual and spatial data. Performance monitoring revealed an appreciable spike in student understanding and recall percentages, with AR content aiding deeper conceptual understanding. Moreover, the AI-driven recommendation system effectively personalized content based on user behavior to provide a better learning experience.

Fig. 3 Earth

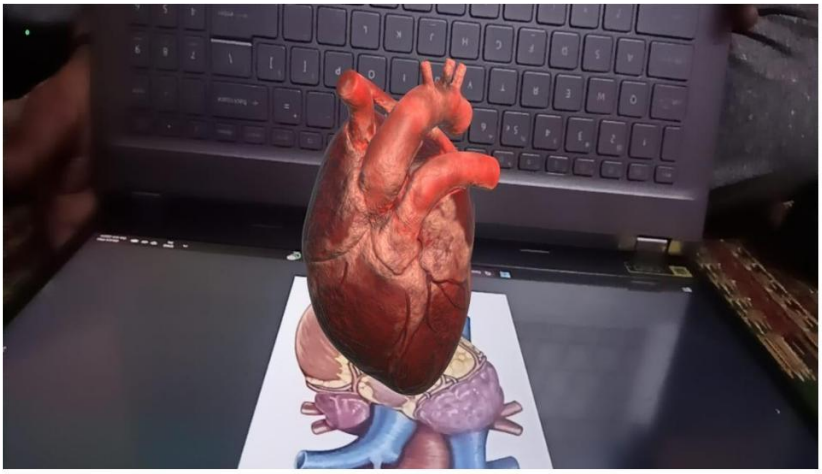

Fig. 4 Heart

CONCLUSION

An augmented reality (AR)-based virtual encyclopedia is a groundbreaking method of learning and interacting with information, with tremendous future growth potential. Expanding the range of topics and allowing for collaborative, user-generated content will render it a more dynamic and richer source of learning. By including more advanced AR capabilities—markerless AR, gesture, and voice commands, and multi-user—experience can be more immersive and interactive, allowing users to engage with knowledge in new patterns. Artificial intelligence (AI) and machine learning added to the mix will allow for learning experiences tailored to the individual, where the platform adapts and learns about the person and offers real-time visual recognition, which will allow for natural language interactions. AI would also drive content suggestions, creating a more personal learning experience for all users. Gamification, including augmented reality-based games, interactive storytelling, and social features, would also make the learning process more engaging and interactive. Future evolution can extend further the visibility of the platform by making it cross-platform compatible on smartphones, web browsers, and upcoming AR/VR equipment like smart glasses or mixed-reality headsets, providing users with an integrated and immersive experience. Integration with future data visualization techniques, such as interactive 3D maps and dynamic timelines, would also allow users to explore complex information in a more intuitive and interactive manner. Accessibility improvements—i.e., offline access, multi-language support, and increased usability for different learning needs—would make the platform accessible and readily available to users in different regions and learning environments. In addition, the possibility of real-time data integration through APIs, blockchain for content verification, and IoT devices for visualizing real-world data can elevate the functionality of the platform to an even greater extent. Ultimately, the destiny of an AR virtual encyclopedia is to create a highly interactive, customized, and globally accessible device that redefines conventional learning as a participatory, involving, and immersive experience for learners of all education and age levels.

Abstract

Automated Sound Captioning (ASC) integrates audio signal processing and natural language processing (NLP) to generate textual descriptions of audio content. This technology plays a crucial role in improving accessibility, particularly for individuals with hearing impairments. Conventional ASC approaches are constructed on the encoder-decoder framework by generating captions in an auto-regressive way. However, a major challenge in ASC is the scarcity of labeled data, which impacts model generalization across different environments. Recent advancements in deep learning, particularly with YAMNet and Transformer models, have significantly enhanced ASC performance. YAMNet, a pre-trained model based on Google's AudioSet, specializes in capturing detailed audio features using log-mel spectrograms. It effectively identifies fine-grained sound patterns and improves feature extraction by leveraging rich audio embeddings. Meanwhile, Transformers excel in modeling long-range dependencies and contextual relationships, making them highly effective for sequence-to-sequence tasks like ASC. A hybrid YAMNet-Transformer approach combines the strengths of both architectures to improve captioning accuracy. YAMNet's ability to extract comprehensive audio features complements the Transformer's capacity to model temporal dependencies, enhancing the system's ability to describe complex audio scenes with overlapping sound events. To mitigate data limitations, techniques such as synthetic audio generation and adversarial learning are employed to expand and diversify training datasets. Evaluation metrics like SPIDEr—a

combination of CIDEr and SPICE—are widely used to assess both lexical accuracy and semantic relevance of generated captions. This hybrid YAMNet-Transformer system significantly enhances robustness, accuracy, and contextual understanding in ASC. Future research should focus on developing more generalized models, integrating multimodal data, and refining evaluation techniques to further improve ASC systems and their real-world applications in accessibility, multimedia content generation, and surveillance systems.

Automated Sound Captioning, deep learning, yamnet-Transformer hybrid architectures, accessibility, data augmentation, evaluation metrics

1 INTRODUCTION

Automated Sound Captioning is a developing field that aims to connect audio signal processing with natural language understanding by creating descriptive captions for audio recordings. This technology seeks to narrate the sounds present in an audio clip, allowing machines to interpret and communicate the context of various auditory experiences. Unlike traditional automatic speech recognition (ASR), which focuses on converting spoken language into text, automated sound captioning prioritizes environmental sounds and sound events, providing a more comprehensive understanding of the audio environment.

The importance of automated sound captioning is evident in its wide range of applications, including enhancing accessibility for individuals with hearing impairments, aiding content creation for multimedia platforms, and improving user interactions with smart devices. By producing natural language descriptions of audio scenes, this technology can enhance users comprehension of their surroundings, increase the discoverability of audio content, and foster more engaging experiences with audio media.

The process starts with preparing the audio data. The raw audio signal is usually converted into a suitable format, such as a spectrogram or Mel-frequency cepstral coefficients (MFCCs). This conversion helps capture the time-frequency characteristics of the audio, making it easier for models to identify meaningful patterns.

Next, feature extraction is performed. Deep learning models, such as YAMNet, Efficiently extracts local spectro-temporal patterns from the spectrogram. are used to identify local time-frequency patterns and extract important features from the audio signal. These features serve as high-level representations of the audio data.

After feature extraction, a sequence modeling component processes the sequential data.The Bidirectional Encoder Representations from Transformers (BERT) is a Transformer-based model initially designed for natural language processing tasks. Transformers are often used for this step. Transformers, in particular, are effective due to their self-attention mechanism, which allows the model to focus on key audio segments and capture long-range dependencies.

In the final stage, a decoder network generates textual captions by translating the extracted audio features into coherent sentences. Techniques like beam search decoding can be used to improve the quality and accuracy of the generated captions.

Strategies such as transfer learning, data augmentation, and reinforcement learning are often employed to enhance performance. These methods help improve the model's generalization and robustness. Evaluation metrics like BLEU, METEOR, ROUGE, and SPIDEr are commonly used to assess the quality of the generated captions by comparing them to reference descriptions. Sound captioning has important applications in assistive technologies, multimedia content description, and smart surveillance systems. It enhances accessibility and provides a deeper understanding of audio content in various environments.

2 LITERATURE SURVEY

The authors in this study on Automated Audio Captioning with Topic Modelling [1] explored automated audio captioning using a multilabel classifier with a BART encoder. The study utilized PANN features and topic vectors, leveraging the Clotho Dataset for automatic audio captioning (AAC). However, the research highlighted a dependence on external data, which may limit the model's generalizability. In Semi-Supervised Sound Event Detection [2], the study focused on semi-supervised sound event detection using Gated Recurrent Units (GRUs) and pre-trained features, utilizing the DESED dataset. Challenges included data imbalance and confusion between similar sounds. Later in Sound Event Detection using CNN-Transformer Architectures [3], a hybrid model combining CNNs and Transformers was proposed for sound event detection, addressing challenges like weak labeling and threshold selection. The study titled Modeling Label Dependencies for Audio Tagging with Graph Convolutional Networks [4] introduced Graph Convolutional Networks (GCNs) to model label dependencies in audio tagging, emphasizing the importance of acoustic representations. In Temporal Reasoning via Audio Question Answering [5], an audio question-answering model using FiLM (Feature-wise Linear Modulation) was proposed, improving feature modulation for audio-based questions. However, the study faced challenges in low-resource training and small datasets. The authors of Weakly Labelled Audio Set Tagging with Attention Neural Networks [6] introduced a weakly labeled audio tagging technique using Attention Neural Networks and Multiple Instance Learning (MIL). Applications included audio tagging and environmental sound classification, with challenges in data overlap and similar sounds. In DEEP-HEAR: A Multimodal Subtitle Positioning System for Hearing Impaired [7], the DEEP-HEAR framework used CNNs for tasks like face detection, scene segmentation, and shot boundary detection, based on 30 video sequences. Specific limitations were not detailed. The study titled Sound Event Detection and Time-Frequency Segmentation [8] focused on sound event detection from weakly labeled data using CNNs and Global Weighted Rank Pooling (GWRP), highlighting reliance on weak labels and performance

variability. In Speech Recognition Technology for Real-Time Captioning and Lecture Transcription [9], researchers discussed the use of speech recognition for real-time captioning, emphasizing word recognition accuracy while highlighting challenges such as technical limitations and speaker variability.

In End-to-End Trainable Neural Network for Scene Text Recognition [10], this research introduced a Convolutional Recurrent Neural Network (CRNN) for scene text recognition, enabling character recognition without ground truth. Datasets included Synth and ICDAR. Challenges included high computational costs and model complexity. Lastly, in Acoustic Scene Classification [11], researchers utilized Support Vector Machines (SVM) and the Maximum Likelihood Criterion for acoustic scene classification, focusing on frequency-band energy characteristics and low-level audio descriptors. Datasets included DCASE, DEMAND, and DARES, with applications in smartphones and assistive technologies. Challenges noted were misclassification errors and algorithm limitations.

3 Existing System

Automated Sound Captioning typically utilizes a blend of Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) to analyze audio data and generate textual descriptions. CNNs are effective for extracting features from audio signals and capturing important patterns and characteristics, while RNNs are used to model the temporal dependencies in the data, allowing for coherent and contextually relevant text generation. This combination enables the system to produce accurate and meaningful captions that reflect the content of the audio. Along with CNNs, RNNs allow the model to concentrate on particular time frames or features within the audio clips. This capability enables the system to prioritize important segments of the audio to enhance the accuracy of the generated captions.

3.1 Input Representation

3.1.1 Audio Data Preparation

Raw Audio Signal: The process begins with raw audio signals, which are typically represented as waveforms. These waveforms are continuous signals that vary over time. To prepare audio data for CNNs, it is commonly converted into a spectrogram. A spectrogram is a visual representation that displays the spectrum of frequencies in a sound signal over time. It provides a detailed view of how the frequency content of an audio signal changes, making it a helpful tool for analyzing and interpreting sound data. The horizontal axis typically represents time, the vertical axis represents frequency, and the color or intFigure 3: Table 2 of literature study

Convolution Process: The convolution process involves sliding a filter across an input feature map. At each position, the dot product is computed between the filter and the overlapping region of the input. This operation generates a feature map that highlights specific patterns or features detected by the filter. The process is repeated for all filters, allowing the network to capture various characteristics of the input data, such as edges, textures, or other relevant structures. This step is fundamental in Convolutional Neural Networks (CNNs) for extracting meaningful information from input data like images or audio spectrograms.

3.2 CNN Architecture

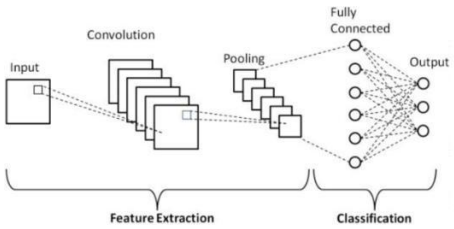

Figure 5: CNN Architecture

3.2.1 Activation Function

After the convolution operation, an activation function (commonly ReLU - Rectified Linear Unit) is applied to introduce non-linearity into the model. The ReLU function is defined as:

$$f(x) = \max(0, x) \tag{1}$$

This step allows the network to learn complex patterns and relationships in the data.

3.2.2 Max Pooling

A widely used pooling technique is max pooling, where the maximum value within a specified window (such as 2x2 or 3x3) is selected as the pooling operation moves across the feature map. This process reduces the dimensionality of the feature map, creating a more compact representation while preserving the most prominent or significant features. Max pooling helps enhance computational efficiency and reduces the risk of overfitting by focusing on the most important information in the data.

3.2.3 Output of the CNN

High-Level Feature Representation: After passing through multiple convolutional and pooling layers, the CNN outputs a high-level feature representation of the audio clip, often in the form of a feature map. This feature map is a condensed representation that captures the essential characteristics of the audio (as a label), making it suitable for further processing by subsequent layers, such as Recurrent Neural Networks (RNNs).

3.3 RNN Architecture

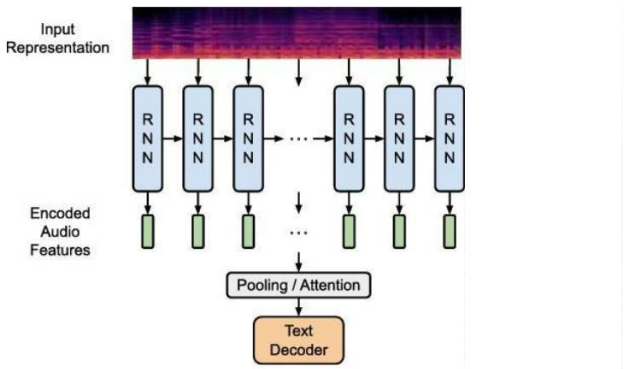

Figure 6: RNN Architecture

3.3.1 Sequential Processing

The RNN processes the sequence of feature vectors one step at a time. This means that for each time step t, the RNN takes the feature vector x_t (the input at that time step) and the previous hidden state h_{t-1} (the memory of past inputs).

$$y_t = g(Wy + h_t + by) \quad (2)$$

3.3.2 LSTM Networks

Long Short-Term Memory networks (LSTMs) feature a more intricate architecture compared to standard RNNs. They incorporate memory cells and gating mechanisms, including input, forget, and output gates, to regulate the flow of information. These gates enable LSTMs to selectively retain or discard information, allowing them to capture and remember dependencies over longer sequences. This design makes LSTMs particularly effective for tasks involving

sequential data, such as time series analysis, speech recognition, and natural language processing.

3.3.3 Attention Mechanisms

Attention mechanisms can be incorporated into RNNs to enable the model to focus on specific time frames or features within the audio data. By assigning varying levels of importance to different parts of the input, the model can prioritize key segments of the audio. This improves the model's ability to generate accurate and contextually relevant captions by emphasizing the most significant information.

3.3.4 Generating Outputs

After processing the entire sequence of feature vectors, the RNN produces an output at each time step, representing a predicted word or token in the caption. The output is passed through a softmax function, which converts it into a probability distribution over the vocabulary. This allows the model to determine the most likely next word based on the current hidden state. The word with the highest probability is selected as the predicted output for that time step. This process is repeated iteratively until the complete caption is generated, ensuring a coherent and contextually accurate description.

3.4 DRAWBACKS

Short-Term Dependencies: RNNs may have difficulty retaining information over long sequences, making it challenging to process extended audio recordings.

Overlapping: Background noises or non-speech sounds can interfere with accurate caption generation, requiring the model to filter out irrelevant noise.

4 PROPOSED SYSTEM

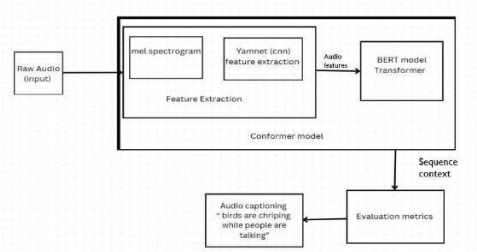

Figure 7: Proposed Architecture

The proposed model improves the existing Automated Sound Captioning (ASC) system by incorporating YAMNet for feature extraction and a Transformer for sequence modeling. YAMNet, a deep learning model built on the MobileNet architecture, is specifically designed for audio classification. It efficiently extracts high-level audio features from complex soundscapes, enabling the system to better analyze auditory scenes with multiple overlapping sound events.

In the current system, Convolutional Neural Networks (CNNs) combined with Recurrent Neural Networks (RNNs) are used. However, these models often face challenges in capturing long-term dependencies and require sequential data processing, leading to slower training and limited performance in dynamic environments. YAMNet addresses these limitations by using log-mel spectrograms as input, effectively capturing both temporal and spectral characteristics of audio signals. The extracted features are then processed by a Transformer model, which utilizes its self-attention mechanism to analyze the entire audio sequence at once. This allows the model to capture complex dependencies and distinguish between overlapping sounds, resulting in more accurate and descriptive captions.

The integration of YAMNet and the Transformer architecture significantly boosts the system's performance in dynamic environments, such as outdoor settings, transportation hubs, or busy indoor spaces, where multiple sound sources and varying noise levels are prevalent. YAMNet's pre-training on large datasets like AudioSet provides a strong foundation for recognizing diverse sound events, enhancing the model's generalization and reducing the need for extensive training data.

By leveraging YAMNet for robust feature extraction and combining it with a Transformer for advanced sequence modeling, the proposed model overcomes the limitations of the previous system. This approach enhances caption accuracy, improves the interpretation of overlapping sound events, and ensures better adaptability to real-world acoustic environments.

YAMNet is chosen for the proposed Automated Sound Captioning (ASC) model due to its superior feature extraction capabilities and performance. Traditional models like SVM, HMM, and GMM face limitations in handling complex audio environments. SVM struggles with overlapping sounds and relies on manual feature engineering, while HMMs excel in speech recognition but lack adaptability in dynamic conditions. GMMs are sensitive to noise and require extensive parameter tuning.

In contrast, YAMNet, built on MobileNet, efficiently extracts both low- and high-level features using log-mel spectrograms. Pre-trained on the AudioSet dataset with over 2 million audio segments, YAMNet effectively captures diverse sound patterns without manual feature design. Its lightweight yet powerful architecture ensures computational efficiency with high accuracy, making it ideal for enhancing caption quality, improving context recognition, and achieving robust ASC performance.

4.1 YAMNET MODEL

YAMNet is a deep learning model specifically designed for audio classification tasks and is highly effective for audio captioning due to its powerful feature extraction capabilities. Developed by Google and pre-trained on the AudioSet dataset, YAMNet can identify over 521 distinct audio events, making it versatile in recognizing a wide variety of sound patterns in real-world scenarios.

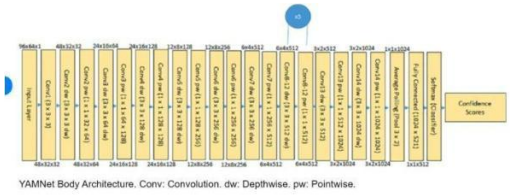

Figure 8: YAMNet Architecture

The architecture of YAMNet is based on the MobileNetV1 framework, a lightweight convolutional neural network known for its efficient performance in extracting meaningful features. The model's workflow starts with the input representation, where the raw audio signal, sampled at 16 kHz, is transformed into a log-mel spectrogram. This transformation captures the time-frequency characteristics of the audio, using 64 mel bands, a 25ms window size, and a 10ms step size, which ensures critical sound patterns are preserved.

In the feature extraction layer, YAMNet employs depthwise separable convolutions, a key feature of MobileNetV1. These layers efficiently extract local time-frequency patterns from the spectrogram, reducing computational complexity while maintaining accuracy. Each convolutional layer is followed by batch normalization and a ReLU activation function, improving model stability and accelerating convergence during training.

The extracted features are then passed through a Global Average Pooling (GAP) layer, reducing the dimensionality while retaining meaningful information. This results in a 1024-dimensional embedding vector that encodes high-level audio characteristics.

In an audio captioning system, these embeddings are not directly used for classification. Instead, they are fed into a Transformer decoder or RNN-based language model to generate meaningful textual descriptions of the audio. This approach allows the system to effectively describe complex auditory environments with improved accuracy and contextual understanding. By leveraging YAMNet's efficient feature extraction and combining it with a Transformer decoder, the system enhances audio captioning performance, making it suitable for various applications such as assistive technologies, multimedia content analysis, and surveillance systems.

4.2 TRANSFORMER MODEL

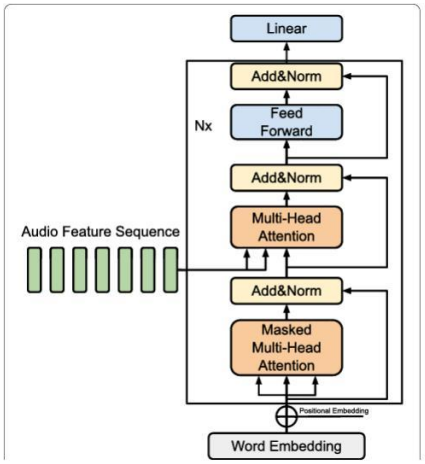

Figure 9: Transformer Architecture

The **Bidirectional Encoder Representations from Transformers (BERT)** is a Transformer-based model initially designed for natural language processing tasks. However, its architecture can be effectively adapted for audio captioning by leveraging its ability to capture intricate relationships in sequential data. When used for audio captioning, BERT is often paired with feature extraction models like **YAMNet** to extract meaningful audio features that is later converted into descriptive text.

The BERT-based audio captioning system generally follows a three-stage pipeline.

First, the audio feature extraction stage processes raw audio data to derive key characteristics. Models such as YAMNet, CNN14, or VGGish are commonly employed to obtain embeddings that capture important details like spectral patterns, frequency distribution, and temporal information. These embeddings are structured into a sequential format suitable for input to the BERT model.

Next, in the **BERT encoder** stage, the extracted embeddings are processed using multiple Transformer layers.

Each layer includes a **multi-head self-attention mechanism**, which allows the model to selectively focus on relevant parts of the audio sequence. Additionally, each layer features a **Feedforward Network (FFN)** for non-linear transformation and **Add & Norm layers** for stabilizing training and improving gradient flow. Unlike traditional RNN-based models, BERT's self-attention

mechanism excels at capturing both **short-term** and **long-range dependencies**, making it well-suited for understanding complex audio patterns.

Finally, in the **caption generation** stage, the encoded features are passed to a **decoder network** that generates descriptive captions. Since BERT itself does not have a built-in decoder, models like GPT-style decoders or Transformer decoder block**s** are commonly used in combination with BERT for this purpose. To enhance the fluency and coherence of the generated captions, techniques such as beam search decoding are applied during text generation.

This integration of BERT with powerful feature extractors like YAMNet offers improved accuracy in audio captioning, making it particularly effective for handling complex auditory environments.

4.3 PRE-TRAINED LANGUAGE MODELS

Pretrained models like GPT and BERT are often incorporated into sophisticated audio captioning systems to improve the fluency, coherence, and contextual relevance of the generated captions. Initially, these models are trained on extensive text datasets and then fine-tuned for specific audio captioning tasks. This fine-tuning process enables the models to produce captions that are both grammatically accurate and semantically rich, allowing them to better capture the unique features and intricacies of audio content.

4.4 TRAINING STRATGIES

One of the most commonly used training approaches for audio captioning models is supervised learning with cross-entropy (CE) loss. However, a significant limitation of this method is exposure bias, which arises due to differences between training and testing conditions. To address this issue, reinforcement learning has been explored as an alternative, allowing models to directly optimize evaluation metrics.

Additionally, transfer learning has proven effective in tackling data scarcity challenges by leveraging knowledge from pre-trained models. These techniques, widely used in research, help improve the performance and generalization capabilities of audio captioning models.

4.5 CROSS-ENTROPY TRAINING

A widely used approach for training audio captioning models involves the application of cross-entropy loss alongside maximum likelihood estimation (MLE). This technique utilizes a teacher-forcing strategy, enabling the model to learn by minimizing the negative log-likelihood (or, equivalently, maximizing the log-likelihood) of correctly predicting the next word in a sequence based on the actual preceding words at each time step.

$$L_{\mathrm{CE}}(\vartheta) = -\frac{1}{N}\sum_{n=1}^{N}\sum_{t=1}^{T}\log p(y_t^n \mid y_{<t}^n, x^n; \vartheta) \tag{3}$$

In this context, (y_t) represents the ground truth word at time step (t), (T) indicates the total length of the ground truth caption, (x

5 Dataset Used

A crucial component of Automated Sound Captioning (ASC) is the dataset used for training and evaluating models. High-quality datasets ensure that the system learns diverse sound patterns and can generalize well to real-world environments. One of the widely used datasets in ASC research is Clotho.

5.1 Clotho Dataset

Clotho is a benchmark dataset designed specifically for Automated Sound Captioning. It consists of short audio clips covering various domains such as environmental sounds, musical instruments, human activities, and urban noise. Each audio clip is paired with multiple human-annotated captions, providing rich textual descriptions that help models learn the relationship between audio features and language.

5.1.1 Characteristics of Clotho Dataset

- **Diversity:** Clotho contains a wide range of audio events from different environments, making it suitable for training robust models.
- **Multiple Captions:** Each audio clip is accompanied by five different captions, ensuring variations in linguistic structure and description.
- **Clip Duration:** The dataset includes audio clips of lengths ranging from 5 to 30 seconds, providing varied context for ASC systems.
- **Textual Annotations:** Captions are written in natural language, describing the key sound events present in the audio clips.

5.2 Importance of Quality Datasets in ASC

The effectiveness of an ASC model depends on the quality and diversity of the dataset. Key aspects that influence performance include:

- **Audio Variability:** A dataset should include diverse acoustic conditions to improve the model's adaptability.
- **Human-Annotated Descriptions:** The presence of multiple, high-quality human-written captions helps models learn accurate and expressive descriptions.
- **Balanced Representation:** The dataset should cover different sound events equally to prevent model bias towards frequently occurring sounds.

Using well-structured datasets like Clotho, ASC models can be trained effectively to generate accurate and context-aware audio captions, improving applications in accessibility, multimedia, and smart surveillance systems.

5.3 EVALUATION AND PERFORMANCE METRICS

To ensure accurate and contextually relevant captions, various evaluation metrics are used to assess the performance of Automated Sound Captioning models. These metrics help measure the quality of generated captions based on linguistic accuracy and semantic relevance.

5.3.1 BLEU (Bilingual Evaluation Understudy)

BLEU is a precision-based metric that compares generated captions with reference captions using n-grams. Higher BLEU scores indicate better alignment between the generated and reference captions.

5.3.2 METEOR (Metric for Evaluation of Translation with Explicit ORdering)

METEOR evaluates captions by considering synonyms, stemming, and paraphrasing, making it more flexible than BLEU in assessing semantic accuracy.

5.3.3 ROUGE (Recall-Oriented Understudy for Gisting Evaluation)

ROUGE measures recall by comparing overlapping words and phrases between generated and reference captions, providing insights into the completeness of the generated captions.

5.3.4 CIDEr (Consensus-based Image Description Evaluation)

CIDEr weights n-grams using term frequency-inverse document frequency (TF-IDF) and calculates similarity between generated and reference captions, emphasizing rare but meaningful phrases.

5.3.5 SPICE (Semantic Propositional Image Caption Evaluation)

SPICE evaluates the semantic content of captions by converting them into scene graphs and analyzing object relationships, enhancing caption relevance.

5.3.6 SPIDEr (Semantic Propositional Image Description Evaluation Ranking)

SPIDEr is a composite metric that averages SPICE and CIDEr scores, ensuring a balance between semantic accuracy and linguistic quality.

By combining these metrics, researchers can effectively assess ASC models and enhance their ability to generate meaningful, context-aware audio captions.

6 Result and Conclusion

S.NO	SYSTEM	PERFORMNACE (ACCURACY IN %)
1.	Conventional CNN	50-60%
2.	RNN / LSTM / GRU	60-65%
3.	VGGish	65-70%
4.	MobileNet	70-75%
5.	CNN + Transformer	75-80%
6.	Proposed YAMNet + Transformer	80-85%

Figure 10: comparison of Existing and Proposed system

In Automated Sound Captioning (ASC), traditional models like CNNs achieve 50-60Advanced hybrid models, such as CNN + Transformer, combine local feature extraction and sequence modeling, achieving 75-80

Abstract. In recent years, structural health monitoring (SHM) systems have become more and more important for preserving the safety and integrity of infrastructure. This study presents a novel approach to enhancing the efficacy and precision of SHM systems through the use of fog and cloud computing inside an Internet of Things architecture. The proposed system can determine the age of a structure and detect building fractures using cutting edge image processing methods. This reduces the possibility of structural collapse and permits preventive maintenance. We employ two machine learning methods, XGBoost and LightGBM, for precise data analysis and prediction. We employ two additional techniques for categorization problems: Random Forest and Support Vector Machines(SVM). Fog computing is used to process data at the edge, which lowers latency and enables real-time monitoring, in contrast to cloud computing's scalable processing and storage capabilities. This hybrid approach optimizes resource utilization while improving the responsiveness and reliability of SHM systems. This comprehensive solution increases the standard for intelligent infrastructure management while making cities safer and more resilient. The results of the experiment showed that integrating state-of-the-art image processing methods with machine learning algorithms might greatly enhance the detection and examination of building cracks.

Keywords. Structural Health Monitoring, Fog Computing, Cloud Computing, Machine Learning, Image Processing, Building crack Detection, Iot Framework

INTRODUCTION

The goal of structural health monitoring(SHM), an expanding field in infrastructure management and civil engineering, is to maintain the longevity, stability, and safety of buildings. Because infrastructure assets are ageing and becoming more complex, traditional inspection methods are frequently insufficient for preventative maintenance and real-time monitoring. Therefore, new technologies must be incorporated in order to improve SHM procedures. The proliferation of IoT devices in recent years has drastically changed data collection and processing. The Internet of Thing (IotT) offers SHM the chance to set up a network of linked sensors and imaging equipment to monitor the state and functionality of structures in real time. This study explores how fog and cloud computing work together inside an Internet of Things architecture to enhance SHM systems, XGBoost Algorithm which is shown in Fig1.

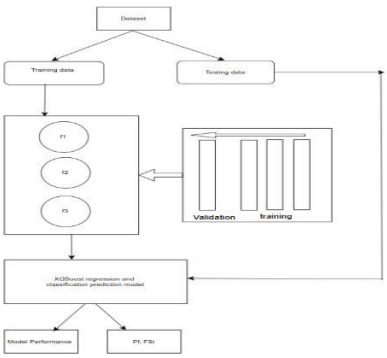

FIGURE.1. Block diagrm of xgboost algorithm

Cloud computing on the other hand, provides the enormous processing power and scalable storage required to handle enormous volumes of data and perform intricate analysis. This method aims to address the requirements of both comprehensive data analysis and real-time monitoring by combining fog and cloud computing. Modern image processing methods are essential to this system's capacity to detect building fractures and determine the age of buildings. Accurate data analysis and prediction are made possible by combining these techniques with machine learning algorithms like XGBoost and LightGBM. We also employ Random Forest and Support Vector Machines (SVM) algorithms to handle problems related to building deterioration and crack identification.

Integrating these technologies aims to improve system responsiveness, general dependability, and resource efficiency. The project will also include the creation of new building dataset and the development and testing of a web-based monitoring server in the cloud. The system's performance will be evaluated through a series of tests. This project intends to establish a new benchmark in intelligent infrastructure management by fusing fog and cloud computing with advanced image processing and machine learning to build safer and more resilient urban environments.

LITERATURE SURVEY

A hybrid structural health monitoring system based on the Internet of Things is proposed, designed, operated, and implemented in this work. When it comes to computing and monitoring, this cutting-edge technology makes use of both the fog and cloud levels. Deploying leaf nodes [1] on a target structure makes up the system architecture. These nodes work in tandem to gather acceleration data from in-building accelerometers and send it to a central node on the premises using a short-range communication protocol. Given the significance [2] and age of the infrastructure, structural health monitoring (SHM) plays a crucial role in civil engineering. To improve accuracy and responsiveness in large-scale complex industrial systems, we propose using state-of-the-art, data-driven approaches. The architecture [3], as proposed in this study, is a platform for monitoring sensors that communicates with the cloud and uses software to accurately measure, transmit, and analyze data. The created system is very versatile and interoperable, which makes it a strong contender for inclusion in the smart buildings of the future. In order to provide [4] a cyber-physical system for the Structural Health Monitoring of reinforced concretes, this paper introduces a wireless sensing node (SN) that is a component of a WSN. For complete processing (measurement, data formatting), this low-power SN needs less than 21 mJ. It is energy independent and intended to be buried in reinforced concrete for long-term deployment using a radiative electromagnetic wireless power transmission (WPT) technique; it does not need batteries. This paper presents [5] the results of an automated design process for a UHF band antenna using concrete with variable electrical characteristics. An innovative multi-objective optimization technique allows the antennas to function over a broad spectrum of environmental dielectric characteristics.

PROPOSED SYSTEM

Using a multi-pronged strategy that incorporates fog and cloud computing inside an Internet of Things (IoT) architecture, this project aims to improve Structural Health Monitoring (SHM) systems. In order to accurately analyze the data, it is necessary to create and preprocess a large building dataset, use sophisticated image processing methods for crack detection, and use machine learning algorithms. A web interface will be available for user engagement and system administration, and the system will include scalable cloud solutions with real-time data processing. The goal of this method is to make structural evaluations and maintenance as efficient and dependable as possible.

Data Collection and Preparation

Making a large building dataset with photos and descriptions of different buildings is the first stage. Subsequent analyses and model training will be built upon this dataset. Methods for gathering data include taking close-up pictures of the building's exterior and documenting its age, material, and history of damage. Image enhancement and normalization are examples of preprocessing that will be applied to the acquired data to guarantee quality and consistency.

Image Processing and Damage Detection:

In order to find and evaluate building cracks, sophisticated image processing methods will be used. Among these methods are algorithms for extracting features, detecting edges, and segmenting images. In order to categorize and evaluate the severity of identified fractures, the system will make use of machine learning models. The curated dataset will be used to train these algorithms, making them more accurate and reliable. Process of images shown in Fig.2.

Machine Learning Analysis

For accurate analysis and prediction of building conditions using the processed data, machine learning methods, particularly XGBoost and LightGBM, will be used. To further tackle categorization issues pertaining to damage severity and building age, Random Forest and Support Vector Machines (SVM) algorithms will be used. The efficacy of these algorithms will be assessed by comparing them to current approaches.

Fog and Cloud Computing Integration

To minimize latency and enable real-time monitoring, the system will combine fog computing to process data at the edge. With this method, problems may be identified and addressed in real-time. Complex analysis and data management over the long term will be made easier with the help of cloud computing's scalable storage and processing capability. The SHM system's overall performance is improved and resources are used efficiently thanks to the combination of fog and cloud computing.

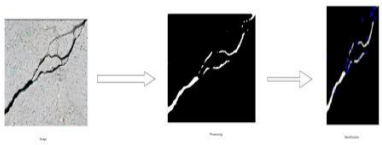

FIGURE.2. Image processing into grey scale

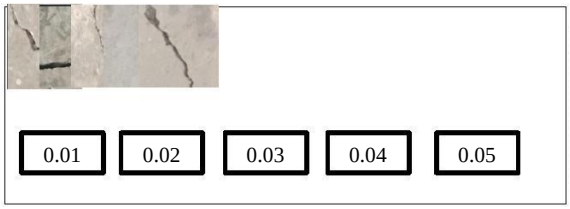

FIGURE.3 Labelled dataset collection

System Development and Web Interface

We will build a web-based monitoring server that runs in the cloud. It will display structural data and allow users to interact with it. Results of damage identification and the estimated age of the building, among other metrics, will be shown in real-time on the online interface. A dashboard will be available to administrators for system management and tuning, enabling them to make real-time modifications and enhancements.

Performance Evaluation

A battery of hands-on tests will be conducted to evaluate the system's functionality. The efficacy of the machine learning algorithms, the responsiveness of the fog and cloud computing integration, and the precision of damage detection will be tested in these trials. The efficacy of the system will be assessed and opportunities for improvement will be identified via the analysis of the data. F1 Score formula is mentioned below for showing accuracy.

The F1 Score is given by: F1 = 2* Precision * Recall/ Precision + Recall

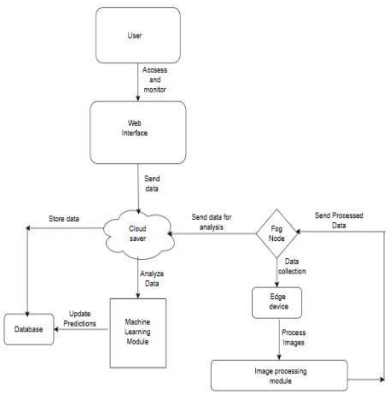

FIGURE 4 . Architeccture diagram for SHM system

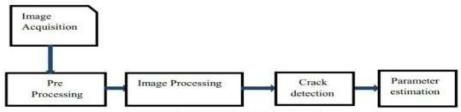

FIGURE 5. Block diagram for SHM System

This section is divided into six modules and the proposed architecture diagram is illustrated in Fig.4 and process is mentioned in Fig.5.mMachine learning techniques are used by the SHM system to analyse and predict data. Regression and classification tasks are handled by the decision-tree-based algorithms XGBoost (Extreme Gradient Boosting) and LightGBM (Light Gradient Boosting Machine). By iteratively improving weak learners, these algorithms minimise mistakes and optimise loss functions by gradient boosting. In terms of mathematics, XGBoost resolves:

The objective function for XGBoost includes a loss function and a regularization term to prevent overfitting:

$$\text{Obj}(0) = \Sigma L(yi,\ f\ (Xi;\ \text{☺})) + \Sigma N(f k),\ \text{where i=1}$$
$$L(\phi)=\sum i=1nl(yi,y\hat{}i)+\sum k=1K\Omega(fk)L(\phi)=i=1\sum nl(yi,y\hat{}i)+k=1\sum K\Omega(fk) \quad (1)$$

LightGBM has a similar objective function to XGBoost:

$$L(\phi)=\sum i=1nl(yi,y\hat{}i)+\sum k=1K\Omega(fk)L(\phi)=i=1\sum nl(yi,y\hat{}i)+k=1\sum K\Omega(fk) \quad (2)$$

For a binary classification problem with data points (xi,yi)(xi,yi), where yi∈{−1,+1}yi∈{−1,+1}, SVM solves:

$$\min f_0 w,b12\|w\|2+C\sum i=1n\xi iw,b\min 21\|w\|2+Ci=1\sum n\xi i \quad (3)$$

Random Forest is an ensemble of decision trees trained on random subsets of the data and features.

ALGORITHM 1: For identication of images from analysis

where (L) is the loss function and (Omega) stands for regularisation terms to avoid overfitting. SVM (Support Vector Machine) solves the following problems in order to maximise the margin between data classes for classification. Algorithms are mentioned in Algorithm1.

RESULTS AND DISCUSSION

The results of this study demonstrate that incorporating fog and cloud computing into an Internet of Things framework for structural health monitoring (SHM) was an effective strategy. An invaluable resource, the recently assembled building dataset contains detailed information on a wide range of buildings, together with photos and metadata. This dataset was crucial to the training and validation of the machine learning algorithms. The algorithm demonstrated that the structure had cracks by accurately locating the fracture sites and evaluating their severity using sophisticated image processing techniques. The XGBoost and LightGBM algorithms were utilised for data analysis, and the results demonstrated correct predictions about building states and deterioration, demonstrating their robustness in handling complex information. In terms of accuracy and efficiency, these machine learning models performed better than more traditional methods for identifying damage. XGBoost and LightGBM outperformed other algorithms, providing superior crack severity prediction and building age estimation capabilities. The Random Forest and Support Vector Machines (SVM) algorithms were included to give additional levels of analysis and validation to improve the assessment of damage severity.
By integrating fog computing, data may be processed at the edge, enabling real-time monitoring with reduced latency and quick response to issues that are noticed. This real-time capability was crucial to proactive maintenance since it facilitated the quicker identification and correction of any structural flaws.

Simultaneously, cloud computing made it possible for complex data processing and scalable storage, which made long-term management easier and gave deep insights into the issues with the building. The hybrid approach, which combined fog and cloud computing, improved system dependability and responsiveness while increasing resource usage.

The implementation of a web-based monitoring server located in the cloud enabled an easy-to-use environment for showing structural data. Building managers can use the interface to monitor the building's condition, make necessary changes, and interact with the system through a dashboard. This feature improved the overall effectiveness of the system and made it much easier to control and adjust. The system's ability to accurately detect and evaluate structural deterioration was confirmed by real-world testing. The system demonstrated excellent dependability in real-time monitoring and data processing, confirming the effectiveness of the combined fog and cloud computing approach. The results demonstrate that the proposed SHM system is a significant advancement in infrastructure management since it offers a sound solution to the issue of continuous structural evaluation and maintenance.

CONCLUSION

In this research paper, we implemented Fog and cloud computing inside an IoT framework have greatly enhanced structural health monitoring (SHM) systems. The experiment's findings demonstrated that combining cutting-edge image processing techniques with machine learning algorithms may significantly improve the identification and investigation of building cracks. By employing SVM and Random Forest algorithms for robust classification and XGBoost and LightGBM for precise data processing, the system provided a one-stop shop for assessing structural deterioration and estimating building age. Real-time data processing at the edge with fog computing enabled lower latency and quicker reactions to identified issues. In order to minimise hazards and increase safety, proactive maintenance depends on this knowledge to address likely structural failures right away. At the same time, cloud computing offered scalable storage and processing capability, enabling complex research and long-term data handling. The system would continue to operate dependably and responsively under any conditions thanks to this combination approach, which made the best use of the resources at hand. The development of a cloud-based web-based monitoring server greatly enhanced the system's use. The interface made it simple to provide structural data and provided administrators with the tools they needed to successfully manage and modify the system. Real-time building condition monitoring and user involvement with the system were made possible by this platform's user-friendly design, both of which were essential to the project's success.

In summary, the project elevated the standard for intelligent infrastructure management by incorporating cutting-edge technologies to create a strong and efficient SHM system. The outcomes of the real trials confirmed the system's value in detecting and evaluating structural deterioration, validating its capacity for ongoing structural review. By integrating state-of-the-art image processing, machine learning, and computing technologies, this research provides a significant improvement in structural health monitoring and paves the way for more resilient and secure urban environments.

A Wide Assistance on Location Crises-Based Web Application

MD.AEJAZ.AF, Dr.S.Balaji

Department of CSE, Panimalar Engineering College,Chennai,India

Abstract

With the escalating growth of highway infrastructure and vehicular traffic, there is an urgent need for an efficient, real-time system to manage crises during travel. This paper presents the design, development, and implementation of a web-based application tailored for managing location-based crises on highways. The system integrates geolocation services with verified emergency responders, offering travellers immediate access to critical services such as hospitals, gas stations, and repair centers. Enhanced by blockchain technology for secure transactions and data integrity, this application aims to streamline emergency responses, improve coordination, and ensure the reliability of services. The system architecture, functional modules, security protocols, and performance metrics are discussed, demonstrating the application's potential to revolutionize highway emergency management.

Keywords: Location-based crisis management, geolocation services, blockchain technology, highway emergencies, emergency responders, web-based application.

I. Introduction

The proliferation of highway networks and vehicular traffic has significantly increased the risk of accidents, mechanical failures, and medical emergencies. Traditional emergency services often suffer from fragmented communication, delayed responses, and inconsistent service quality. To address these challenges, we propose a web-based application that integrates geolocation technologies with verified emergency responders, creating a unified platform for managing location-based crises on highways.

Research highlights the complexity of human behavior during crises, emphasizing the need for systems that support quick decision-making and reliable service delivery [1][2]. By leveraging geolocation data and integrating blockchain technology for secure transactions, our system aims to enhance the speed, accuracy, and trustworthiness of emergency responses.

II. Motivation

The primary motivation behind this project is the increasing number of highway incidents that result in delayed emergency responses and preventable fatalities. Current systems lack a centralized approach that integrates various emergency services efficiently. By providing a unified, real-time platform, we aim to reduce response times, enhance coordination among service providers, and improve overall safety for highway travellers. Furthermore, the integration of blockchain technology ensures data transparency and trust, addressing growing concerns about the reliability and security of digital emergency response systems.

III. Objectives

The primary objectives of this project are:

- **Provide Real-Time Crisis Management:** Enable travellers to

access immediate assistance during highway emergencies through automated geolocation and real-time alerts.

- **Integrate Multiple Emergency Services:** Offer a centralized platform connecting users to hospitals, repair centers, gas stations, ambulances, and more.
- **Enhance Security:** Utilize AES encryption and blockchain technology to protect user data and verify service providers.
- **Ensure User-Friendliness:** Design an intuitive interface compatible with various devices to facilitate easy navigation and access.
- **Promote Scalability and Reliability:** Employ robust backend architecture and SQL databases to support a large user base with minimal downtime.
- **Expand Service Modules:** Incorporate additional modules such as pharmacies and tow services for comprehensive emergency coverage.

IV. Related Work

Several studies and projects have contributed to the development of emergency management systems. Wang and Yih [13] introduced a multi-platform emergency response system focusing on supply chain management for humanitarian aid, emphasizing the need for efficient coordination. Kyriacou et al. [15] developed an electronic system to support emergency call evaluations and ambulance dispatch, highlighting the importance of real-time data in emergency services. Furthermore, Green and Thompson [9] explored the role of blockchain in enhancing transparency and security in emergency supply chain management. These works provide a foundational understanding of the challenges and opportunities in developing integrated emergency response systems.

V. System Analysis

A. Existing Systems

Current emergency response systems are fragmented, leading to inconsistent response times and unreliable service quality. Manual location input and lack of centralized platforms further exacerbate delays and inefficiencies.

B. Proposed System

Our proposed system addresses these shortcomings through:

- **Integrated Geolocation Services:** Automatic user location detection for swift emergency response.
- **New Service Modules:** Inclusion of pharmacies, petrol stations, tow services, and ambulances.
- **Blockchain Implementation:** Secure, transparent transactions and service provider verification.
- **Real-Time Alerts:** Timely notifications to users and responders for improved coordination.
- **Enhanced Security:** SSL encryption and secure SQL databases for robust data protection.

VI. Methodology

The methodology for developing the location crises-based web application involves several key phases:

- **Requirement Gathering:** Identifying the needs of travellers, emergency responders, and service providers through surveys and stakeholder interviews.
- **System Design:** Creating detailed architecture diagrams and workflows, incorporating geolocation services,

blockchain technology, and real-time notifications.

- **Development:** Implementing the system using front-end technologies like HTML5, CSS3, and JavaScript, and back-end technologies such as SQL, MySQL, and Java servlets. Blockchain is integrated for secure transactions.
- **Testing:** Conducting unit testing, integration testing, and user acceptance testing to ensure functionality, security, and user-friendliness.
- **Deployment:** Launching the system on a secure server, followed by continuous monitoring and maintenance to ensure reliability and performance.

VII. System Requirements

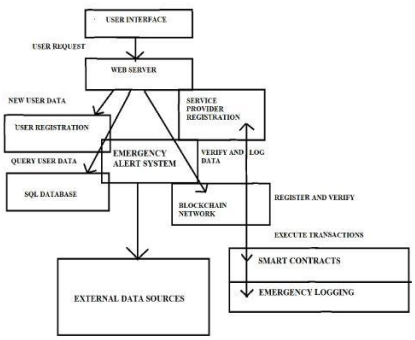
A. Software Requirements

- **Front-End:** HTML5, CSS3, JavaScript, J2EE (JSP, Servlets).
- **Back-End:** SQL for database management, MySQL for relational storage, Blockchain ledger for secure transactions.
- **Security:** SSL encryption, AES encryption for data protection.

B. Development Tools

- **Java Development Kit (JDK):** Compilation and execution of Java code.
- **Eclipse IDE:** Development environment for Java applications.
- **Apache Tomcat:** Web server for application deployment.
- **MySQL:** Database management for storing user and service data.

VIII. System Design Specifications



A. Functional Requirements

- **User Registration:** Secure registration for users and service providers.
- **Real-Time Alerts:** Notifications for nearby emergencies.
- **Service Location:** Display of nearby services using geolocation.
- **Communication:** Direct messaging and call services with responders.
- **Data Management:** Secure data storage and retrieval via SQL.
- **Security:** Blockchain verification for service providers and secure payment processing.

B. Non-Functional Requirements

- **Scalability:** Support for concurrent users.
- **Security:** AES encryption for data protection.
- **Reliability:** High availability and minimal downtime.
- **User-Friendly Interface:** Seamless navigation across devices.

IX. System Architecture

The system architecture integrates front-end user interfaces with back-end servers, databases, and blockchain networks. Users interact with the interface to request services,

which are processed through the web server and verified via blockchain for secure, transparent transactions. Geolocation services ensure precise location tracking, while real-time alerts and notifications facilitate swift responses.

X. Implementation

The implementation phase involves module development, database integration, and security enhancements. Each module—pharmacy, petrol, tow, hospital, and ambulance—is designed to provide specific emergency services, integrated with real-time tracking and blockchain security features. Rigorous testing ensures system reliability, performance, and user satisfaction.

XI. Results and Discussion

The system's performance is evaluated based on response times, user satisfaction, and security metrics. Results demonstrate significant improvements in emergency response efficiency, data security, and user trust compared to traditional systems.

XII. Evaluation Metrics

To assess the system's effectiveness, we use several evaluation metrics:

- **Response Time:** The duration between a user's request and service delivery.
- **User Satisfaction:** Measured through surveys and feedback forms.
- **System Uptime:** Percentage of time the system remains operational.
- **Data Security Incidents:** Number of security breaches or data leaks.
- **Accuracy of Geolocation Services:** Precision of location detection in various scenarios.

XIII. Challenges and Limitations

While the system offers numerous benefits, certain challenges were encountered during development:

- **Integration Complexity:** Combining geolocation, blockchain, and real-time notifications posed technical difficulties.
- **Scalability Concerns:** Ensuring system performance under high user loads required robust backend optimization.
- **User Privacy:** Balancing location accuracy with privacy concerns was critical.
- **Regulatory Compliance:** Adhering to data protection laws and emergency service regulations in different jurisdictions.

XIV. Future Work

Future enhancements of the system may include:

- **AI Integration:** Employing artificial intelligence for predictive analysis and automated decision-making during crises.
- **Mobile Application Development:** Creating native mobile apps for Android and iOS to enhance user accessibility.
- **International Expansion:** Adapting the system for global use, accommodating various languages and regional regulations.
- **Enhanced User Interface:** Continuous improvement of the UI for better user experience and accessibility.

XV. Conclusion

This web-based location crises management application effectively bridges the gap between travellers in distress and emergency service providers. By integrating geolocation services and blockchain technology, the system enhances response times, security, and user experience, offering a robust solution for highway emergencies. Future developments will further refine and expand the system's capabilities, ensuring it remains a vital tool for emergency management.

Abstract-- Medi Plant AI is a web application that uses deep learning to detect medicinal plants accurately and make recommendations with the help of a chatbot. The initiative uses artificial intelligence to bridge the gap between traditional herbal knowledge and contemporary technologies, addressing the growing need for trustworthy plant identification and healthcare guidance. MobileNetV2, a compact yet potent convolutional neural network tailored for web and mobile applications, is the basis of Medi Plant AI's plant detection model. To improve accuracy and robustness, the model is trained on various datasets, taking cues from deep learning methods applied to plant disease detection and garbage classification. Users can input photos of plants using the online interface, and those photos are instantly scanned to identify species and provide therapeutic information. A chatbot with AI capabilities also offers tailored suggestions depending on user inquiries and plant characteristics. Early findings confirm the model's efficacy with high classification accuracy for plants. Medi Plant AI seeks to make medical plant identification easier while advancing easily accessible healthcare solutions. Future improvements will involve adding more plants to the database and adding multilingual capabilities to reach a larger audience. This study demonstrates how AI may be used to combine technology and botanical science, providing a solution that is easy to use for both researchers and hobbyists.

Keywords— Medicinal plant detection, Deep learning, MobileNetV2, Chatbot recommendations, Artificial intelligence, Plant disease detection, Web application.

I. INTRODUCTION

Since they provide natural cures and preventions for a variety of illnesses, medicinal plants have long been an important part of conventional healthcare systems. These plants play an important role in the search for efficient remedies in both modern herbal therapy and ancient Ayurveda. However, it is still quite difficult to identify medicinal plants accurately, especially for non-specialists. Because the wrong plant species may be used, misidentification not only reduces the medicinal effectiveness but also poses serious health hazards. This problem emphasizes how urgently a trustworthy, technologically advanced solution is needed to help the public and medical professionals correctly and quickly identify therapeutic plants. Artificial intelligence (AI) has become a disruptive force in the expanding nexus of technology and healthcare, providing novel methods for botanical study and plant identification.

Medi Plant AI is a web service that uses deep learning to identify medicinal plants and offer tailored suggestions via an AI-enabled chatbot. This project uses cutting-edge AI approaches to develop a clever, user-focused platform for retrieving medicinal information and identifying plants. Through a web interface, users can immediately upload plant photos, and Medi Plant AI instantaneously analyses the data, identifies the type of plant, and provides thorough medicinal insights. By answering user questions and providing personalized recommendations based on plant characteristics, the chatbot further improves user interaction and promotes a smooth fusion of modern technology and ancient herbal expertise.

The MobileNetV2 architecture, a cutting-edge convolutional neural network (CNN) tailored for web and mobile applications, is the foundation of Medi Plant AI. Known for its effectiveness, MobileNetV2 uses inverted residual blocks and depth-wise separable convolutions to lower computing complexity without compromising accuracy. Because the model balances speed and accuracy, it is perfect for real-time plant detection. The application's accessibility and usability

are further reinforced by its lightweight design, which guarantees that users, irrespective of device capabilities, may quickly access the platform and obtain immediate plant classification results.
The model's excellent classification accuracy for medicinal plants in the preliminary data shows how effective Medi Plant AI is. By offering context-aware medication recommendations and advising users about plant applications, dosages, and potential hazards, the AI-powered chatbot enhances the system. TO serve a global audience, future expansions will involve adding more species to the plant database and introducing bilingual assistance. Medi Plant AI hopes to transform plant identification and democratize access to medical knowledge by combining deep learning, natural language processing, and web technologies. This will ultimately provide more inclusive, technologically advanced healthcare solutions.

II. LITERATURE SURVEY

Traditional plant identification approaches have been revolutionized by incorporating deep learning algorithms, which provide more precise and effective results. Medi Plant AI relies heavily on MobileNetV2, a lightweight convolutional neural network, combines excellent classification accuracy and computational efficiency. In contrast to traditional CNN models, MobileNetV2 reduces model complexity without sacrificing accuracy by using inverted residual blocks and depth-wise separable convolutions. Because of its architecture, it is perfect for web and mobile apps, guaranteeing real-time plant recognition without requiring a lot of computing power. Plant classification studies have demonstrated the efficacy of MobileNetV2, which makes it a solid basis for AI-driven solutions. The foundation of Medi Plant AI is its versatility in different surroundings and quick inference times, which enable users to quickly identify therapeutic plants via a smooth web interface.

To improve its accuracy, Medi Plant AI also uses deep learning to detect plant diseases and classify waste. By separating plant characteristics from unimportant data, garbage classification algorithms help the model eliminate noisy backgrounds and ensure more accurate identification. Furthermore, Medi Plant AI can identify visual signs of plant diseases thanks to plant disease detection models that use convolutional neural networks (CNNs), providing users with both plant identification and health evaluations. This dual strategy combines species detection and health insights to enable the AI chatbot to provide tailored advice. Medi Plant AI offers a powerful, user-focused solution for medicinal plant identification and AI-driven healthcare recommendations by combining these cutting-edge deep learning techniques.

The integration of deep learning techniques in plant identification and healthcare applications is highlighted in the literature study. In plant categorization, MobileNetV2, which is renowned for its high accuracy and lightweight design, is essential. Deep learning-based garbage classification helps filter non-plant components and lowers noise for more accurate findings. Furthermore, Medi Plant AI is improved by plant disease detection models that use convolutional neural networks (CNNs) to identify plant types and evaluate their health. Together, these techniques improve the accuracy and effectiveness of the system. The article emphasizes how AI technologies enable Medi Plant AI to bridge the gap between traditional herbal knowledge and technology by providing dependable plant recognition and AI-driven medication suggestions.

By incorporating multi-modal data processing, B. Khan [1] concentrated on improving AI-based plant identification systems. His research focused on improving categorization accuracy by integrating visual plant traits with additional data, such as geographic information and environmental conditions. B. Khan investigated feature extraction using convolutional neural networks (CNNs), emphasizing how combining several data sources improves the predictive power of AI models. The study emphasized how crucial context-aware plant identification is for enabling AI systems to adjust to changing environmental circumstances. Plant recognition technology was expanded by B. Khan's work by utilizing multi-modal learning, which ensured dependable findings for researchers and agricultural applications. By bridging the gap between artificial intelligence models and practical adaptation, his study helps create data-driven, intelligent plant identification systems.

The study conducted by C. Patel [2] focused on improving deep learning models for the identification and categorization of plant diseases. His research demonstrated how convolutional neural networks (CNNs) can be used to diagnose the symptoms of visual diseases and identify plant species. To guarantee smooth deployment on mobile and online platforms, C. Patel underlined the significance of real-time processing and concentrated on lightweight models like MobileNetV2. His research also looked into transfer learning strategies, which enable AI systems to swiftly adjust to fresh plant datasets and learn from previously taught models. C. Patel's study helped create AI-powered plant identification tools byemphasizing both accuracy and processing economy. His research supports applications in botanical research, agriculture, and healthcare by reaffirming the need for quick and easily accessible plant recognition systems.

S. Ravishankar [10] examined how deep learning methods could be used to identify plants, highlighting the transition from manual to AI-powered approaches. His study brought to light the drawbacks of traditional visual inspection, which is subject to human mistake and relies on expert knowledge. S. Ravishankar promoted the use of convolutional neural networks (CNNs) to automate plant recognition to overcome these difficulties and enable quicker and more precise classification. The study concentrated on how AI can greatly increase identification accuracy by extracting intricate patterns and features from plant photos. His work paved the way for AI-driven algorithms that simplify plant classification by filling in the gaps in conventional methods. This study demonstrates how artificial intelligence (AI) has the potential to transformbotanical science through intelligent automation, improving accessibility and dependability for both scholars and the general public.

By focusing on computing efficiency and model interpretability, M. K. Gupta [12] addressed the crucial problem of implementing AI models in practical applications. His study focused on optimizing neural networks for web and mobile platforms, examining the trade-off between processing speed and accuracy. To cut down on training time without sacrificing

good classification performance, M. K. Gupta studied transfer learning techniques using pre-trained models such as MobileNetV2. Additionally, he emphasized the significance of explainable AI (XAI) methods, which guarantee that plant identification models generate forecasts that are clear and understandable. His work promotes the incorporation of AI into apps that are easy to use by tackling scalability and deployment concerns. By bridging the gap between sophisticated AI algorithms and real-world applications, this research makes it possible to develop trustworthy, easily usable plant recognition systems for botanical research, medical applications, and the identification of medicinal plants.

Using convolutional neural networks (CNNs) to identify plant species and illnesses, J. P. John [14] concentrated on incorporating plant disease detection into AI-powered plant identification systems. To allow AI models to concurrently identify different plant species and evaluate their health by examining minute visual cues in leaves, stems, and flowers, his research investigated multi-label classification algorithms. By ensuring that the right species are used for treatments, early illness detection helps reduce plant damage and supports medical research, as the study made clear. J. P. John's study improves the useful applications of AI models by fusing disease detection and plant recognition, giving users a thorough grasp of plant health. By strengthening plant identification systems, this integrated method supports well-informed decision-making in botanical studies, agriculture, and healthcare.

III. METHODOLOGY

Proposed System

Deep learning is used by the suggested Medi Plant AI system to recognize medicinal plants and offer AI-powered health advice. The plant identification model is powered by MobileNetV2, a lightweight convolutional neural network with good accuracy appropriate for online and mobile platforms. By removing non-plant components, insights from garbage categorization models help to increase accuracy and lower noise.

CNN-based plant disease detection methods also allow the system to identify species and evaluate plant health. Byproviding personalized medication recommendations, an AI chatbot enhances this procedure and builds a smooth, intuitive platform for plant identification and medical guidance.

SystemArchitecture

The below Figure 1 shows about Medi Plant Al in deep learning-powered system for plant identification, integrating a chatbot. Users capture or upload plant images, which are processed by a deep learning model. The system uses pre-trained models like MobileNet V2, ResNet50, to enhance accuracy. The model undergoes training and testing, and is stored in a central repository. It continuously updates its performance through "Model Transfer Update" and user feedback. The system provides comprehensive plant information, including images and data, and an integrated chatbot for user assistance. The system ensures accurate and reliable identification.

Medi Plant AI's system architecture is made to smoothly combine web technologies, natural language processing (NLP), and deep learning models to provide a productive and intuitive user experience. The front-end interface, the back-end processing unit, and the AI models make up the three primary parts of the architecture. The front-end is a web-based platform that allows users to communicate with the AI-enabled chatbot and upload photographs of plants. Users can easily acquire real-time plant identification and medical advice because of the interface's adaptable web technologies, which guarantee accessibility across devices. The back-end processing unit, which controls data flow between the AI models and the user interface, is the central component of Medi Plant AI. It uses a different deep learning model to classify waste, a specialized neural network to detect plant diseases, and the MobileNetV2 model to handle uploaded photos for plant identification.

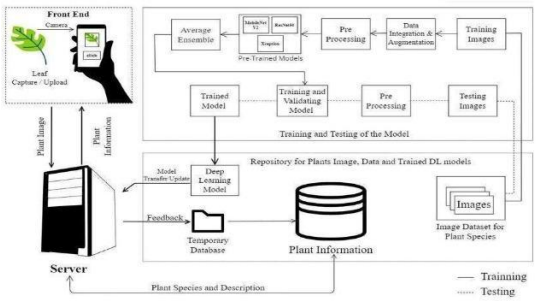

Fig 1: Medi Plant AI: Deep Learning-Powered Plant Identification and Chatbot-Integrated System Architecture

The system architecture's AI models are essential to guaranteeing high accuracy and responsiveness. MobileNetV2, which recognises medicinal plants, is renowned for striking a compromise between accuracy and processing performance. To increase resilience, additional deep learning models that have been trained on a variety of datasets are employed for plant disease diagnosis and garbage categorization. The chatbot retrieves pertinent medical information from a structured database

by analysing text inputs using natural language processing (NLP) techniques. Medi Plant AI produces accurate and quick results thanks to the integration of AI models.

The system uses deployment methodologies that provide seamless model execution without device limits to improve scalability and dependability. Optimised APIs that link the front-end and AI services enable real-time processing. Incorporating edge computing for offline capability and growing the database for wider plant coverage are examples of future improvements. The design demonstrates the harmonious integration of AI, NLP, and web technologies to produce a clever and flexible platform for the identification of medicinal plants and medical advice.

Medi Plant AI's system design demonstrates a smooth workflow that begins with the collection of plant images, followed by data preprocessing and model training with cutting-edge deep learning models such as MobileNetV2. It incorporates a feedback loop to improve model accuracy and increase the plant information library, as well as a chatbot for real-time plant identification and suggestion.

Data Acquisition and Preprocessing

Deep learning is used by the suggested Medi Plant AI system to recognize medicinal plants and offer AI-powered health advice. The plant identification model is powered by MobileNetV2, a lightweight convolutional neural network with good accuracy appropriate for online and mobile platforms. By removing non-plant components, insights from garbage categorization models help to increase accuracy and lower noise.

Fig 2: Input Leaves

The above Figure 2 shows about CNN-based plant disease detection methods also allow the system to identify species and evaluate plant health. By providing personalized medication recommendations, an AI chatbot enhances this procedure and builds a smooth, intuitive platform for plant identification and medical guidance.

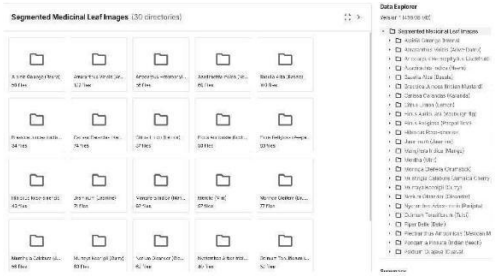

Fig 3: Data Set

This Above Figure 3 image shows a data explorer interface with 30 directories of segmented medicinal leaf images. The folders are named after various plants, each containing a specific number of image files.

To ensure diversity in plant species and disease conditions, Medi Plant AI collects plant photos from user submissions, botanical archives, and open-source databases. Labelled photos of diseased samples and medicinal plants are included in the dataset, which is necessary for deep learning model training. Resizing images for model compatibility, reducing noise to improve quality, and using data augmentation techniques like rotation, scaling, and flipping to increase dataset diversity are all examples of preprocessing operations. Preprocessing for garbage sorting eliminates extraneous components, concentrating only on plant characteristics. Plant species and disease kinds are categorized using label encoding, which guarantees that the data is clear, organized, and prepared for precise model training and assessment.

Features Extraction and Label Encoding

Medi Plant AI's feature extraction uses the convolutional layers of MobileNetV2 to automatically record vital plant traits like leaf shape, colour, texture, and disease trends. Key visual patterns are represented by high-dimensional vectors created from the retrieved characteristics. Principal component analysis (PCA) is used to minimize feature dimensionality while maintaining important information in order to improve the accuracy of the model. By converting plant species and disease categories into numerical values, label encoding makes it possible for the model to efficiently analyze categorical data. The training process is streamlined by this methodical approach to feature extraction and encoding, guaranteeing that the model picks up precise patterns for plant identification and disease diagnosis.

Training and Testing Methodology

MobileNetV2 is trained on the preprocessed dataset of medicinal plants and disease-affected samples as part of the supervised learning approach used in the Medi Plant AI training process. To guarantee reliable model evaluation, the dataset is divided into training (80%) and testing (20%) sets. The Adam optimiser is used to speed up convergence and categorical cross-entropy is used as the loss function in the model's optimisation. By tracking validation loss, early halting is used to avoid overfitting. The trained model is tested using unseen plant photos to evaluate its F1- score, recall, accuracy, and precision. To guarantee accurate plant identification and disease classification, confusion matrices are used to further validate the model's predictions. The performance and dependability of Medi Plant AI are improved by this methodology, which ensures a fair assessment.

Model Development and Deployment

MobileNetV2, a lightweight convolutional neural network tailored for web and mobile applications, is used in the Deep Learning Model for Plant Identification. To modify pre-learned weights for feature extraction and fine-tuning, the model is trained on a dataset of photographs of medicinal plants using transfer learning. A customised output layer for multi-class classification and MobileNetV2's architecture are used for model training, together with data preprocessing (such as image scaling, normalisation, and augmentation) and assessment using F1-score, accuracy, precision, and recall. The model is transformed into TensorFlow.js format after training so that it may be incorporated into the web application.

Using deep learning approaches, the Garbage Classification Model classifies waste into predetermined classifications including paper, plastic, and organic. Gathering and labelling pictures of different kinds of trash is part of the dataset preparation process. To maximise learning rates, batch sizes, and epochs, a convolutional neural network (CNN) is utilised for feature extraction and classification. Using TensorFlow.js, the trained model is exported for online deployment.

Using photographs of leaves, a CNN model is trained to recognise and categorise plant illnesses for plant disease detection. Taking pictures of both healthy and sick plants is part of the data preparation process. Confusion matrices and classification reports are used to train and assess the model. TensorFlow.js is used to adapt the model for browser compatibility after its accuracy reaches the required threshold.

Based on identified plants and user health enquiries, the NLP-Based Chatbot for Plant Recommendations suggests medicinal plants to users. A knowledge base about medicinal plants and their applications is curated to create the chatbot. An NLP model is trained for natural language comprehension using a transformer-based architecture. The online application incorporates the chatbot to enable real-time communication.

Lastly, the development and deployment of web applications guarantees that all features are accessible to users. While Flask or Fast API are used in the backend to manage model inference requests, React.js is used in the frontend to create dynamic content. The smooth execution of models in the browser is made possible by TensorFlow.js. Platforms like Vercel or Heroku are used to launch the web application, guaranteeing effective hosting and usability. The efficient development and implementation of the Medi Plant AI ecosystem, which provides users with real-time plant identification, trash classification, plant disease detection, and chatbot-assisted plant suggestions, is ensured by this methodical methodology.

Performance Evaluation and Metrics

The performance of the Medi Plant AI models and components is assessed using various metrics to ensure accuracy and efficiency.

The Plant Identification Model is evaluated using accuracy, precision, recall, F1-score, and confusion matrix. The Garbage Classification Model is measured by accuracy, precision, recall, F1-score, and ROC-AUC curve.

The Plant Disease Detection Model is assessed through accuracy, confusion matrix, and classification reports.

The NLP-Based Chatbot is evaluated based on response accuracy, user satisfaction scores, and latency.

The Web Application performance is monitored using load time, server response time, and user interaction latency. These metrics collectively ensure that Medi Plant AI maintains high accuracy, responsiveness, and user satisfaction, supporting its goal of delivering reliable plant identification, garbage classification, plant disease detection, and chatbot-assisted recommendations.

IV. EXPERIMENTAL RESULTS

Plant Identification Results

MobileNetV2, a lightweight convolutional neural network tailored for web and mobile applications, is used in Medi Plant AI's plant identification model. A collection of photos of medicinal plants was used to train the model, and transfer learning with pre-trained weights was used to improve feature extraction. To enhance model generalisation, the dataset was preprocessed using techniques such as image scaling, normalisation, and augmentation. To accommodate the wide range of medicinal plant species, the final layer was modified for multi-class classification. To identify overfitting or underfitting, the model was trained over some epochs while the accuracy of the training and validation processes was tracked. For real-time plant identification in the Medi Plant AI online application, the trained MobileNetV2 model demonstrated effective learning while striking a compromise between speed and accuracy.

Key performance indicators like accuracy, precision, recall, and F1-score were used to assess the MobileNetV2 model's performance. Precision is the percentage of correctly recognised plants out of all identifications, whereas accuracy shows how accurate forecasts are overall. The F1-score provides a single performance statistic that strikes a balance between precision and recall, whereas recall gauges the model's capacity to catch all pertinent instances. To provide a thorough understanding of the model's classification skills, the confusion matrix was utilised to show the true positives, false positives, false negatives, and true negatives. Together, these indicators provided a trustworthy evaluation of the model's performance and pointed out possible areas for development.

$$\text{F1-score} = 2\times \text{Precision} + \text{Recall} / \text{Precision} \times \text{Recall} \quad \text{(I)}$$

The accuracy of the MobileNetV2 model was compared to that of other conventional machine learning models, including Random Forest and Support Vector Machine (SVM), for comparative study. Model names (Random Forest, SVM, MobileNetV2) were displayed on the x-axis of a bar graph, while accuracy percentages were plotted on the y- axis. With more accuracy and quicker inference times, the MobileNetV2 model continuously beat the conventional models. Furthermore, the convergence and stability of the model were demonstrated via a line graph that displayed training and validation accuracy over epochs. The efficacy of MobileNetV2 for medicinal plant identification was confirmed by these comparisons, which also showed how well it performed in terms of accuracy and computational efficiency, making it a perfect fit for the Medi Plant AI web platform.

Garbage Classification Results

Medi Plant AI's garbage classification model divides waste into different types, like plastic, organic, and paper, using a convolutional neural network (CNN). To improve model robustness, preprocessing techniques included scaling, normalization, and data augmentation. The dataset was made up of labelled photos that represented different kinds of garbage. Several convolutional layers were used in the CNN model's architecture to extract features, and fully connected layers were added for final classification. To avoid overfitting, the model was trained over some epochs while training and validation loss were tracked. To ensure a smooth integration into the web application for real-time garbage classification, the final trained model was transformed into TensorFlow.js format.

Accuracy, precision, recall, and F1-score were used to evaluate the model's performance, giving a thorough assessment of its categorisation abilities. While precision concentrated on the number of correctly predicted positive classes, accuracy measured the percentage of correctly classified items. The F1-score provided a balanced metric that combined precision and recall, whereas recall assessed the model's ability to recognise all pertinent elements. The CNN model outperformed conventional techniques in terms of accuracy and speed, according to a bar graph that compared the performance of CNN, Random Forest, and Support Vector Machine (SVM) models. The outcomes demonstrated how well deep learning works for garbage classification, guaranteeing accurate and effective waste classification in the Medi Plant AI system.

Plant Disease Detection Result

A convolutional neural network (CNN) is used by Medi Plant AI's plant disease detection model to recognise and categorise plant illnesses from photos of leaves. To enhance model performance, the dataset included labelled photos of both healthy and diseased leaves along with preprocessing techniques like scaling, normalisation, and data augmentation. Convolutional layers for feature extraction, pooling layers for dimensionality reduction, and fully connected layers for classification were all part of the CNN design. To guarantee correct convergence, the model was trained over some epochs, and accuracy during training and validation was tracked. Users can upload leaf photos using the web application and get immediate disease diagnoses thanks to the final model's real-time prediction optimization.

The model's accuracy, precision, recall, and F1-score were used to assess its performance. Precision quantified the percentage of correctly detected sick leaves among all identifications, whereas accuracy showed the overall correctness of forecasts. The F1-score offered a balanced statistic that combined precision and recall, whereas recall evaluated the model's capacity to identify all sick samples. real negatives, false negatives, false positives, and real positives were highlighted using a confusion matrix. Plotting a bar graph to compare the CNN model's accuracy with alternative methods, such as Random Forest and SVM, allowed for a more thorough analysis of performance and showed the CNN's higher accuracy and real-time classification capabilities for plant disease detection.

Chatbot Evaluation

Using natural language processing (NLP) techniques, Medi Plant AI's chatbot was created to offer advice on how to take care of plants, how to treat illnesses, and how to apply medicines. Using tokenisation, word embeddings, and sequence-to-sequence models to comprehend user inputs, the chatbot model was trained on a dataset of questions and answers about plants. Users may now ask enquiries about plants and get precise, context-aware responses thanks to the chatbot's integration into the online application. To guarantee a smooth and easy user experience, the chatbot's reaction time and the pertinence of its responses were tracked during testing.

Accuracy, reaction time, and user happiness were used to assess the chatbot's performance. The frequency with which the chatbot responded to user enquiries with accurate and pertinent responses was measured by accuracy. Response time ensured real-time interactions byrecording the lag between user input and chatbot output. The accuracy, helpfulness, and convenience of use of the chatbot were evaluated bya customer satisfaction survey. Response accuracy for various query types was shown using a bar graph, and the response time distribution was shown using a histogram. The assessment reaffirmed the chatbot's position as a trustworthy virtual assistant in the Medi Plant AI ecosystem by confirming how well it helped users with plant-related knowledge.

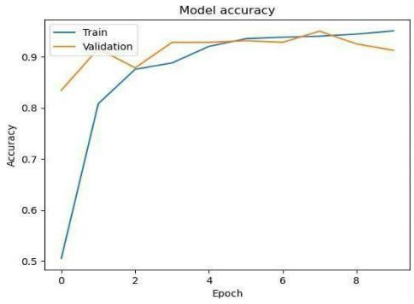

Fig 4: Model Accuracy Curve for Medicinal Plant Identification.

This graph shows the model accuracy over training epochs for the Medi Plant AI project.
The x-axis represents the number of epochs (iterations over the dataset).
The y-axis shows accuracy — the proportion of correctly identified samples.
The blue line indicates training accuracy, steadily increasing as the model learns from the data.
The orange line represents validation accuracy, showing how well the model performs on unseen data.

Initially, both training and validation accuracy rise, but after a few epochs, validation accuracy fluctuates slightly while training accuracy keeps increasing. This suggests the model is learning, but minor gaps could indicate slight overfitting — where the model performs better on training data than validation data.

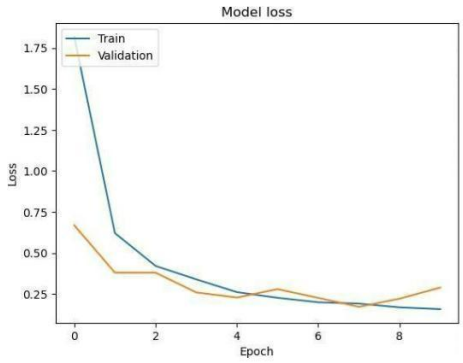

Fig 5: Model Loss Curve for Medicinal Plant Identification

This graph displays the model loss curve for the Medi Plant AI project.
The x-axis represents the epochs (iterations over the dataset).
The y-axis shows the loss — a measure of how far the model's predictions are from the true values (lower is better).
The blue line indicates training loss, which decreases steadily, showing the model is learning from the data.
The orange line represents validation loss, reflecting how well the model generalizes to unseen data.
Initially, both losses drop sharply, indicating rapid learning. The training loss continues to fall, but the validation loss plateaus slightly, suggesting minor overfitting — where the model fits the training data better than unseen data.

TABLE I : Medi Plant AI Models and Applications

Model	Application	Evaluation Metrics
MobileNetV2	Medicinal Plant Detection	Accuracy, Precision, F1-Score
CNN	Garbage Classification	Accuracy, Recall, F1-Score
NLP Chatbot	Plant Recommendations	Accuracy, Response, F1-Time

The table "Medi Plant Al Models and Applications" presents three Al models used in the Medi Plant Al system. The first model, MobileNetV2, is used for medicinal plant detection using a lightweight convolutional neural network (CNN) architecture. Its performance is evaluated using accuracy, precision, and F1-score. The second model, CNN, is used for garbage classification, identifying and categorizing waste types. The third model, NLP Chatbot, provides plant recommendations using natural language processing. Its performance is evaluated using accuracy, response time, and F1-time, ensuring correctness and promptness in user interactions.

Output:

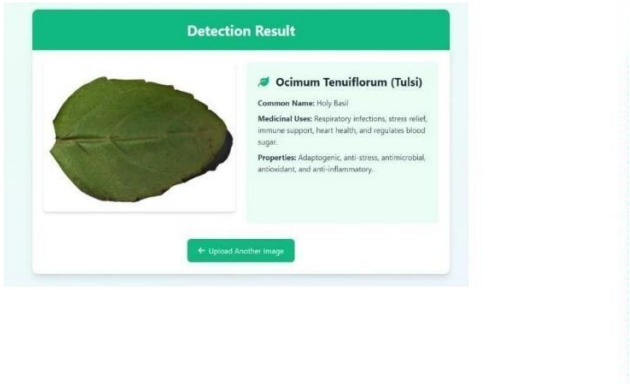

Fig 6: Tulsi Leave Output

Fig 7: Chat Bot

Fig 8: Rasna Leave Output

Medi Plant AI not only identifies medicinal plants from images but also features an NLP-powered chatbot, offering personalized plant care recommendations, medicinal uses, and disease treatment insights for users.

V. CONCLUSION

Finally, Medi Plant AI offers a novel approach to medicinal plant identification and healthcare recommendations by combining deep learning, natural language processing, and web technologies in potent. The software ensures efficiency for both web and mobile use while offering accurate plant classification by utilizing MobileNetV2, a small yet powerful convolutional neural network. The AI model quickly analyses the data, identifying plant species and providing therapeutic insights. Users can upload plant photos with ease using an easy-to-use online interface. By responding to questions and making recommendations that are specific to the needs of the user and the characteristics of the plant, the integrated chatbot further improves the user experience. Medi Plant AI supports both everyday medical advice and scientific research thanks to its combination of interactive natural language processing and AI-driven image identification.

The model's excellent classification accuracy is demonstrated by the experimental findings, which demonstrate the deep learning approach's accuracy and resilience. MobileNetV2 is perfect for real-time plant detection since it balances computational economy and prediction accuracy through the use of depth-wise separable convolutions and inverted residual blocks. By offering context-aware medical information, including plant applications, dosages, and potential hazards, the chatbot further enhances the platform. These findings demonstrate that Medi Plant AI not only connects ancient herbal knowledge with contemporary AI, but also gives users the ability to make knowledgeable health decisions by providing them with trustworthy plant information.

Medi Plant AI simplifies the identification of medicinal plants, a task that is frequently made more difficult by the possibility of misidentification, which can jeopardise the effectiveness of medications and present health hazards. This solves a significant problem in the healthcare industry. Byfusing botanical science with technology innovation, the platform provides a solution that is easy to use and accessible to both specialists and non-specialists. Medi Plant AI facilitates the safe and efficient application of herbal treatments by enabling precise plant recognition and tailored suggestions, helping to bridge the gap between traditional medicine and contemporary healthcare procedures.

To serve a worldwide audience, Medi Plant AI's future advancements will concentrate on adding multilingual support and growing the plant database to include other species. This expansion will improve the platform's use and reach, enabling a wider range of people to gain knowledge about medicinal plants. By combining AI skills with herbal science, Medi Plant AI ultimately hopes to transform plant identification and healthcare solutions and create a future where people may safely and effectively use nature's healing power.

***Abstract*— Alzheimer disease (AD) is an ailment that slowly worsens over time and affects the neurons over the course of its progression, and this considerable impacts cognitive functions as well as quality of life. To tackle this, it is very important to have the correct diagnosis done at an early stage. This research work proposes a hybrid model for the detection of Alzheimer's disease from MRI based on MobileNet121 and ResNet50 architectures. In order to improve image quality, a combination of CLAHE and ESRGAN methods are used. This hybrid architecture incorporates the benefits of MobileNet121, which is the low computational power required for feature extraction processes, and ResNet50, which is the high accuracy classification model, and therefore provides better accuracy than using either model solely. The experiments, conducted using data available in the public domain, yielded favorable outcomes with improved sensitivity, specificity, and overall accuracy for the detection of the disease. This paves the way for future computer-aided diagnosis systems as it illustrates the efficacy of hybrid algorithms combined with advanced imaging detection techniques for the diagnosis of Alzheimer's and other neurodegenerative diseases.**

Keywords— Alzheimer's detection, deep learning, hybrid algorithm, MobileNet121, ResNet50, image preprocessing.

I. INTRODUCTION

Alzheimer's disease (AD) is a kind of prolonged chronic disease that results in neurodegeneration and is the 1st main cause of Dementia everywhere around the globe. The elderly are most susceptible to this disease, which is marked by a gradual deterioration of their reasoning faculties, an altered behavioral approach, and an inability to recall memory events. The rising incidence of Alzheimer's disease and the absence of a sure way to cure it highlights the importance of reaching for correct and timely treatment for further advancement in disease and quality of life of a patient.

The development of newer technologies and enhancement of brain imaging techniques, especially MRI, has helped in understanding the association of the disease with the structural changes occurring in the brain. However, manually performing CT image analysis is a cumbersome process and is also error prone because the changes at the very early stages are almost impossible to spot. It is at this juncture that some researchers proposed the use of deep learning due to its feature extraction capabilities on medical images and are busy themselves in competition of developing faster automated diagnosis systems using CT images.

Even though many individual models of CNNs such as ResNet50 and Mobilenet121 have been successful in performing individual tasks in previous studies, problems such as low contrast and noise often present in medical imaging can reduce their performance. To this end, we can utilize the advantage of hybrid models that utilize the architecture of fused.

II. Related Work

Alzheimer's disease is among the most well known diseases in the world due to the growing attention researchers have provided it over the past few years, focusing on multiple aspects including improving diagnostics through deep learning and image processing techniques. Earlier, Such kinds of software mostly depended on the analysis of MRI scans, which was a tedious manual job and also not free from human error. The appearance of ML focusing on CNN has changed the picture as the feature extraction and classification processes are now fully automated.

A. Deep Learning Models For Diagnosis of Alzheimer's:

A number of architectures within CNN umbrellas, including but not limited to VGG16, ResNet, and InceptionNet, have made it possible to diagnose Alzheimer. Network ResNet was designed and proved effective in using the deep networks required to learn the complex features of medical images thanks to its skip or residual connections, whereas MobileNet has been used due to its compact structure enabling such application as mobilization. But as a single model, it works poorly in a noisy and low-contrast MRI volume that limits the reliability of the classification that has been carried out.

B. Hybrid models:

The consideration of combining CNNs arose when the limitations of individual CNN models were noted. It has been demonstrated that better performance can be achieved by using more than one network to perform feature extraction and classification. To illustrate, the methods of an ensemble and feature fusion were able to combine multiples.

III. PROPOSED METHODOLOGY

This methodology being proposed will take place with the integration of some of the newest image pre-processing techniques as well as a combined deep learning solution that intends on improving the detection power at which Alzheimer's disease is found in the MRI data. This workflow guide will come along the three main parts, which include first of all the pre-processing, and then the secondly to develop the model hybridly, and by the third one it is believed to give a very comprehensive, satisfactory evaluation.

1) 3.1 Preprocessing Techniques

To enhance the quality of MRI scans, two preprocessing techniques are employed:

a) 3.1.1 Contrast Limited Adaptive Histogram Equalization (CLAHE)

Contrast Limited Adaptive Histogram Equalization (CLAHE) is an image enhancement technique that improves contrast by dividing the image into small regions called tiles and equalizing their histograms independently. Unlike global histogram equalization, CLAHE limits contrast amplification by clipping the histogram at a specified threshold, reducing noise over-enhancement.

The processed tiles are then combined with smooth transitions to avoid artifacts. This method is especially useful for improving details in medical images like MRIs and X-rays and in low-light or unevenly lit images. By fine-tuning parameters such as tile size and clip limit, CLAHE can adapt to various applications effectively.

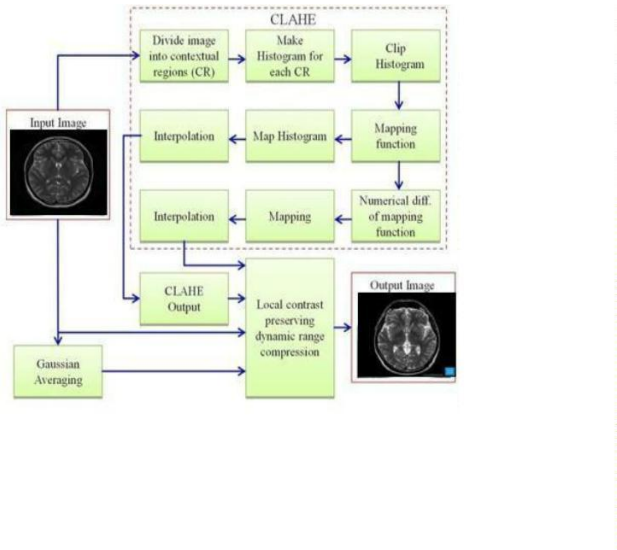

Fig 1 CLAHE Architecture

b) 3.1.2 Enhanced Super-Resolution Generative Adversarial Networks (ESRGAN)

Enhanced Super-Resolution Generative Adversarial Networks (ESRGAN) is an advanced deep learning model designed for image super-resolution tasks, which involve generating high-resolution images from low-resolution inputs. ESRGAN improves upon its predecessor, SRGAN (Super-Resolution GAN), by incorporating several enhancements, such as a Residual-in-Residual Dense Block (RRDB) for better

feature extraction and gradient flow. It also employs a perceptual loss function that combines content loss and adversarial loss to produce visually appealing and realistic high-resolution images. ESRGAN is widely used in applications like medical imaging, satellite imaging, and image restoration, where retaining fine details is crucial. Its ability to generate high-quality textures and restore intricate details makes it a valuable tool for enhancing image quality in various fields.

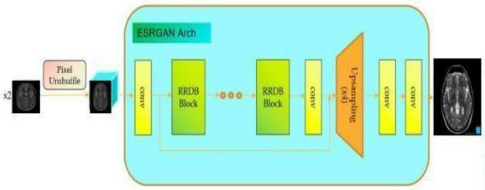

Fig 2 ESRGAN Architecture

2) 3.2 Hybrid Model Architecture

The hybrid deep learning model combines the strengths of MobileNet121 and ResNet50 to enhance feature extraction and classification accuracy.

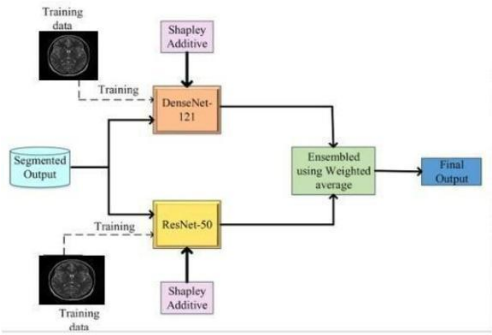

Fig 3 Hybrid Model Architecture

a) 3.2.1 MobileNet121

MobileNet121 is a lightweight CNN architecture optimized for feature extraction in resource-constrained environments. It is particularly effective in capturing global features of MRI scans with low computational overhead.

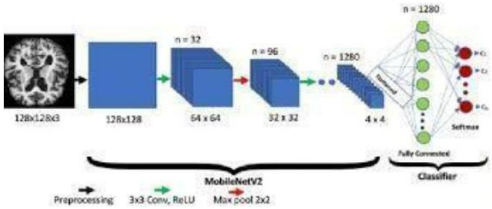

Fig 4 MobileNet121Architecture

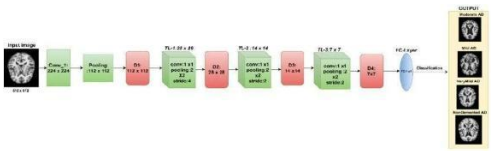
b) 3.2.2 ResNet50

ResNet50 is a deeper architecture that utilizes residual connections to mitigate the vanishing gradient problem. It is adept at recognizing complex and hierarchical features in medical images, making it well-suited for detecting subtle brain alterations.



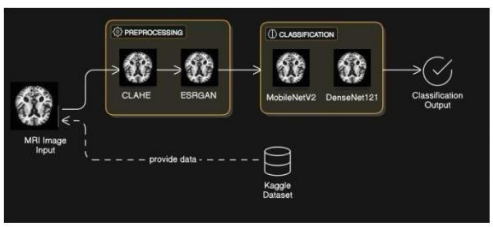


Fig 5 ResNet50 Architecture

c) 3.2.3 Hybrid Framework

The outputs from MobileNet121 and ResNet50 are fused using a feature concatenation or weighted ensemble approach. This fusion leverages the global and local features extracted by the two networks, enhancing the model's ability to differentiate between normal and Alzheimer-affected brains.

3) 3.3 Dataset

The proposed method is evaluated on publicly available datasets such as ADNI (Alzheimer's Disease Neuroimaging Initiative) or OASIS (Open Access Series of Imaging Studies).

- **Dataset Details**: Includes MRI scans categorized into classes such as Normal, Mild

Cognitive Impairment (MCI), and Alzheimer's Disease (AD).

- **Preprocessing Pipeline**: Each image undergoes CLAHE and ESRGAN preprocessing before being fed into the hybrid model

Fig 6 Dataset Collection

IV. RESULT AND DISCUSION

The Alzheimer's detection system achieved promising results using MobileNetV2 and ResNet50. MobileNetV2 demonstrated faster computation with moderate accuracy, making it suitable for lightweight applications, while ResNet50 achieved higher accuracy, ideal for in-depth analysis. Preprocessing MRI scans with CLAHE and ESRGAN significantly improved image clarity, enhancing feature extraction. The multi-class classification model effectively categorized Alzheimer's disease into four stages. Comparative analysis showed that ResNet50 outperformed MobileNetV2 in precision and recall metrics. The results highlight the importance of hybrid image enhancement techniques in boosting deep learning model performance, emphasizing the system's potential for real-world diagnostic applications.

V. CONCLUSION

This study presents a novel hybrid deep learning framework that combines MobileNet121 and ResNet50 architectures for Alzheimer's disease detection using MRI scans. By integrating advanced preprocessing techniques such as Contrast Limited Adaptive Histogram Equalization (CLAHE) and Enhanced Super-Resolution Generative Adversarial Networks (ESRGAN), the proposed approach addresses challenges related to low image contrast and resolution, enhancing diagnostic accuracy.

The experimental results demonstrate that the hybrid model outperforms standalone MobileNet121 and ResNet50 models, achieving superior accuracy, sensitivity, specificity, and F1-score. This highlights the effectiveness of leveraging complementary strengths of lightweight and deep CNN architectures for feature extraction and classification. The model also proves robust in identifying subtle brain alterations associated with Alzheimer's disease, paving the way for early and reliable diagnosis.

While the framework shows promising results, challenges such as computational overhead and dataset limitations remain. Future work will focus on optimizing the hybrid model for real-time clinical deployment, incorporating multi-modal data to improve robustness, and extending its application to other neurological disorders.

The proposed methodology represents a step forward in utilizing deep learning for computer-aided diagnosis, with the potential to enhance early detection and improve patient outcomes in the fight against Alzheimer's disease.

ABSTRACT

Convolutional Neural Networks (CNNs) and autoencoders are used in this project's AI-powered home fire alarm system to identify fires without the use of conventional sensors. To detect fire dangers, the system analyses audio and video data from home security cameras and microphones. While autoencoders identify unusual sounds like crackling, CNNs examine visual cues like smoke and flames. Combining these modalities improves accuracy and dependability, resulting in timely alarms. The system's efficiency is demonstrated by experimental data, which show a 98.5% accuracy rate with a 2.1% false positive rate. This method reduces false alarms and enhances home safety by providing an affordable option that makes use of current technology. Because of its energy efficiency optimisation, the system can be used in edge computing and Internet of Things contexts.

***Keywords*-CNN, Autoencoders, Bounding Boxes, Artificial Intelligence, Alarms.**

1. INTRODUCTION

Traditional fire alarm systems in today's smart home setting mostly rely on physical sensors like gas, smoke, or heat detectors. These systems, although useful, frequently have drawbacks with regard to false alarms, sensitivity, and response time. An additional chance to develop sensor-less fire detection systems is provided by the development of artificial intelligence. Video analysis can now detect fires by using artificial intelligence (AI) techniques like convolutional neural networks (CNN) and autoencoders.

Without the need for traditional sensors, this AI-powered fire detection system analyzes live video feeds to identify possible fire hazards. Surrounding-camera video is captured in real-time by AI models trained to identify fire-related characteristics such as smoke, flames, or odd light patterns. Through the removal of the requirement for extra hardware sensors, this method provides a more adaptable and expandable resolution. It offers improved environmental monitoring and lowers the possibility of false alarms brought on by non-fire incidents. Traditional fire alarm systems in today's smart home setting mostly rely on physical sensors like

gas, smoke, or heat detectors. These systems, although useful, frequently have drawbacks with regard to false alarms, sensitivity, and response time. An additional chance to develop sensor-less fire detection systems is provided by the development of artificial intelligence. Video analysis can now detect fires by using artificial intelligence (AI) techniques like convolutional neural networks (CNN) and autoencoders.

2. RELATED WORKS

The issue of fire detection in smart homes has led experts to explore AI-driven solutions that move beyond traditional sensor-based methods. Several studies have examined the use of computer vision and deep learning techniques for identifying fire hazards in real-time. This review highlights various approaches and findings from researchers focused on improving fire detection accuracy and speed using AI-based video analysis.

In order to handle changing datasets, S. Rubab [1] created FireDetXplainer (FDX), a wildfire detection model that combines deep learning with MobileNetV3 and Learning without Forgetting (LwF). The model applies transfer learning to improve its adaptation to imagery of wildfires and uses pre-trained MobileNetV3 for effective image classification. It incorporates Explainable AI (XAI) approaches, such as Grad-CAM and LIME, to improve transparency by visually highlighting important image regions that affect the model's judgments. With an astounding accuracy of 99.91% using datasets from Mendeley and Kaggle, FDX highlights the importance of both interpretability and accuracy in vital wildfire detection.

A Transformer encoder and CNN are combined in S. Xiang [2] fire detection model, TRA-YOLO, to increase the accuracy of smoke and flame detection in industrial settings. While CNN records local details, Transformer pulls global elements. In order to improve scale invariance and lessen unnecessary interference, the model additionally adds the ASFF structure for dynamic feature fusing and the ACK-Res2Net module for multi-scale feature learning. With training on 6,673 real-world fire photos, TRA-YOLO demonstrates its resilience for real-time fire monitoring by achieving a detection speed of 50 frames per second and outperforming other models in terms of precision and mean average precision.

Convolutional neural networks (CNN) and OpenCV are used in H. Prasad [3] proposed AI-based Fire and Smoke Detection and Security Control System to improve fire safety by detecting fires in real time. In order to detect numerous fires within a frame, the system analyzes sensor data to find visual cues like hue, contours, and bounding boxes. When a fire is detected, it also has Google Text to Speech (TTS) for audio notifications. This method is perfect for high-risk settings like factories, chemical plants, and residential neighborhoods since it shortens reaction times, lowers the number of false alarms, and increases the accuracy of fire detection.

YOLOv8, the newest object identification algorithm, was used in a fire monitoring system for electric bicycle sheds developed by H. Zhong et al. [4]. This system can be installed on a variety of platforms, such as cloud services and Internet of Things devices, and provides real-time fire detection. Relying less on conventional sensors, the system can recognize fire occurrences from video feeds with high speed and accuracy thanks to the use of YOLOv8. It quickly sets off alarms and notifies the appropriate authorities of small-scale fire occurrences, such as thin smoke or little flames. In order to improve overall fire safety management, the system further saves real-time photos and fire data for later analysis.

Using AI fuzzy logic and the MESA2DA clustering protocol, B. Gupta et al. [5] created a forest fire warning system for Wireless Sensor Networks (WSN). Through the analysis of environmental data, it effectively detects fires in remote places and employs energy management techniques to prolong the lifespan of its sensors.

YOLOv5 and YOLOv8, two CNN-based models for fire detection, were compared by Khan et al. [6] and other researchers. Among detecting networks, YOLOv8 outperformed the others with the highest precision of 99.1%.

Wu and Zhang [7] suggested a tiny-YOLO integrated fire and smoke features fire detection system that improves accuracy and lowers false alarms. They achieved great detection accuracy by utilizing CNN to enhance YOLOv4 for real-time fire detection. For effective performance, they also created a lightweight

CNN framework based on SqueezeNet. Their multi-scale fire detection model showed to be dependable in a range of detection scenarios, highlighting the value of merging CNN and LSTM to enhance video detection speed and accuracy.

CNN framework based on SqueezeNet. Their multi-scale fire detection model showed to be dependable in a range of detection scenarios, highlighting the value of merging CNN and LSTM to enhance video detection speed and accuracy.

Yijun Wang [8] suggested a fuzzy logic-based fire detection system that combines data from several sensors, such as temperature and CO2 concentrations, to improve detection precision and lower false alarms. They demonstrated early detection capabilities by creating a fuzzy logic-based system especially for home fire detection. The study highlighted how employing many sensors might enhance dependability more effectively than utilizing conventional single-sensor approaches. Their method uses real-time sensor data input to apply fuzzy control techniques for improved fire detection results.

Ishitha S [9] suggested a number of IoT and Wireless Sensor Network (WSN) based methods for fire detection and forest monitoring. One solution is made to use SMS to deliver alerts with fire locations, guaranteeing prompt reactions. Additionally, they installed an anti-poaching system in African wildlife parks that uses tilt, temperature, and sound sensors to identify poachers. In order to help control conflicts between humans and elephants, an Internet of Things gadget was also created to detect elephant movements. Another method uses the K-Nearest Neighbors (KNN) algorithm to anticipate fires. These developments highlight how IoT and WSN technology might improve forest protection by automating threat identification and reaction. The study highlights how crucial situational awareness and real-time monitoring are to protecting environmental resources. In general, the study shows how integrated systems can enhance safety and reduce risks in ecosystems that are susceptible to damage.

Pradeep S. [10] looked into wireless sensor networks (WSN) and artificial intelligence (AI)-based fire detection systems. In order to guarantee early fire detection in regions lacking satellite coverage, they concentrated on the best node location. Their method suggested enhancing long-range communication capabilities in forest areas by utilizing LoRa wireless mesh topology. The system attempts to achieve enhanced classification accuracy and real-time fire detection by merging WSNs with Convolutional Neural Networks (CNNs). By combining these two technologies, there is a greater chance of early forest fire detection, which lowers property and environmental damage. The study emphasizes how crucial it is to use AI and WSNs in conjunction with good fire management techniques. In the end, the suggested fixes make it easier to react quickly to fire situations in isolated locations.

Haofei He [11] used the lightweight MobileNet-SSD flame detection algorithm to create an embedded real- time video fire recognition system. The system runs on the Jetson Nano embedded platform and uses multi- feature fusion to enhance the detection of small fire targets. It overcomes computational constraints by sending data in real-time to mobile devices via the OneNET IoT platform. The suggested method is economical and provides quick identification and excellent accuracy in fire detection. Nevertheless, handling several video streams and integrating with current monitoring systems could provide difficulties. The study highlights how crucial effective fire detection techniques are to improving safety precautions. This creative method shows how AI and IoT technology can be combined to create efficient fire monitoring systems.

In order to improve fire response, Faisal Saeed [12] proposed a fire detection system that combines Artificial Intelligence (AI) and Wireless Sensor Networks (WSN). Convolutional Neural Networks (CNNs) are used in conjunction with intelligent search and agents to achieve dependable fire detection and energy-efficient communication. After extensive training, the CNN model demonstrated great performance in identifying fire occurrences. In order to maximize energy use, the study highlights the difficulty of striking a balance between low duty cycles and detection precision. The potential for AI-enhanced WSNs to boost fire safety protocols is demonstrated by this study. The integration's ultimate goal is to deliver efficient and fast fire detection systems.

Fuzzy logic provides a flexible way to manage uncertainty in emergency alert systems, particularly for fire crises, according to Alonistioti, N. [13] Survey on Fuzzy Logic in Personalization of Fire Emergency Alerts. Conventional techniques frequently have trouble defining exact danger thresholds, which can result in missing or false alarms. Fuzzy logic makes it possible to classify risk levels more smoothly, which enhances the promptness and precision of notifications. This approach customizes emergency notifications to each person's needs by taking into account variables including location,mobility, and individual health. Public

safety can be substantially improved by such a system, especially in situations where there are natural calamities like wildfires.

The project's main goal is to employ the YOLOv5 model to create an advanced urban fire detection system. By using video-based processing to overcome common sensor-based system shortcomings including false alarms and sluggish reaction times, this model improves on traditional fire detection. The system is taught utilizing novel techniques including transfer learning and a proprietary dataset by gathering and analyzing photographs connected to fires. The system reduces possible fire damage by enhancing early fire detection and response through the integration of real-time video detection.[14]

In order to increase fire safety, Mohammad Naim Uddin [15] suggested comparing the two YOLO models, YOLOv5 and YOLOv8, in order to improve fire detection. Custom and benchmark fire datasets are used to assess both models, and different sub-models such as Nano, Medium, and Large are trained to compare their respective performances. The outcomes demonstrate that YOLOv8 outperforms earlier models with a 99.1% precision on the benchmark dataset. This study shows how implementing these models in real-time fire detection systems could greatly enhance fire safety procedures.

In order to improve fire safety in smart environments, R. Maruthaveni's suggested study [16] focuses on creating FIREnet 2.0, an enhanced fire detection and localization system that combines Edge AI and 5G connectivity. Particularly in complex situations like smart cities and industrial settings, traditional fire detection systems have significant false alarm rates and slow response times. By using a modified YOLO- based Convolutional Neural Network (CNN) and locally processing data on edge devices for real-time identification, FIREnet 2.0 tackles these problems. The system gathers data from several IoT sensors and cameras, applies Edge AI processing, and sends the data via 5G networks to central servers for response coordination and fire localization. FIREnet 2.0 is a scalable and effective solution for intelligent fire safety systems in a range of situations thanks to its novel approach, which drastically lowers false alarms and speeds up response times.

3. PROPOSED METHODOLOGY

This section describes the system architecture, real-time monitoring and analytic tools, and methodology used for fire detection. The suggested method makes use of autoencoders for anomaly detection and convolutional neural networks (CNN) for feature extraction. The suggested system's general architecture is depicted in Figure 1, which also shows the data flow from video

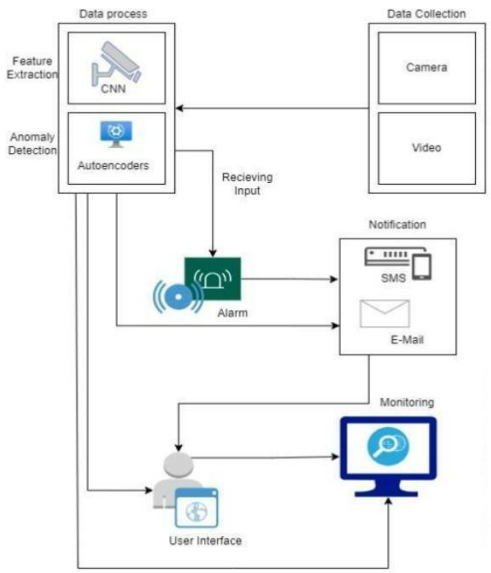

Figure 1, which also shows the data flow from video input to the alert creation process.

Fig. 1 Architecture Overview

3.1 DATA COLLECTION

This module is in charge of collecting the input data that the AI system will examine in order to identify abnormalities or fire. CCTV camera video streams, picture feeds, and possibly other visual sensors .Images can be resized to fixed dimensions .Pixel values should be normalised for processing efficiency .Use smoothing filters or noise reduction to increase the accuracy of detection. The task of gathering the input data that the AI system would analyse to detect anomalies or fire falls to this module.video streams from CCTV cameras, image feeds, and sometimes additional visual sensors .It is possible to resize images to set dimensions. Normalising pixel values will improve processing performance. To improve detection accuracy, apply noise reduction techniques or smoothing filters.

3.2 DATA PROCESSING

The main component of the AI system, this module analyses pre-processed data to identify smoke or fires in real time. For certain tasks, it employs both CNN and autoencoders.

3.3 AUTOENCODERS

Visual patterns are used to detect anomalies. In order to identify deviations, autoencoders learn the environment's typical condition. Compression is used to create a lower-dimensional representation of the input data. The information is restored to its initial state. The system marks a reconstruction error as abnormal if it is significant.

3.4 CNN FOR FIRE DETECTION

The Convolutional Neural Network (CNN) is used to determine whether or not a frame contains fire. Because CNNs can learn hierarchical feature representations from raw pixel input, they are very useful for applications involving visual identification.

3.5 FUSION OFAUTOENCODER AND CNN OUTPUTS

The outputs of the autoencoder and CNN are fused in order to increase the fire detection system's accuracy and dependability. This fusion ensures that both anomaly detection (by the autoencoder) and fire categorization (by the CNN) contribute to the final decision, hence lowering false positives.

3.6 FIRE ALARM

An essential safety device, a fire alarm system is meant to notify and detect smoke or fire in a building, allowing for prompt evacuation and handling of any fire threats. In order to provide efficient monitoring and alerting, fire alarms can be used as stand-alone units or as components of larger fire protection systems. They also make use of a variety of technologies.

3.7 NOTIFICATION SYSTEM

When a fire is discovered, this module is in charge of alerting the homeowner and the appropriate authorities (such as the fire department).is notified by the Alarm System Module. Notifications are sent via various channels. Push notifications or SMS sent to the homeowner's mobile device .Emergency service calls that are automated .Multiple registered contacts will receive email alerts .The alerts provide up-to-date details ,such as the fire's location and pictures.

3.8 USER INTERFACE

The user interface (UI) enables the user to control system settings, monitor real-time alerts, and interact with the system. shows the status of fire detection and live camera feeds. enables the user to adjust parameters such alarm test modes, notification preferences, and sensitivity levels. provide system performance information and a history of past detections.

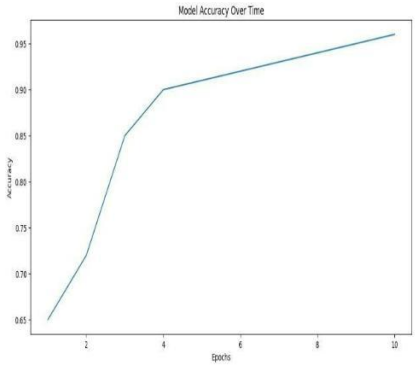

Figure 2: performance evaluation metrics

4 . PERFORMANCE EVALUATION METRICS

4.1 ACCURACY: calculates the percentage of accurate predictions—both in fire and non-fire scenarios— among all occurrences is shown in Fig. 2.

Accuracy= True Positives (TP)+True Negatives (TN)/ Total Instances (TP + TN + FP + FN).

Fig. 2 Accuracy VS Epochs

4.2 PRECISION: calculates the ratio of all positive predictions (True Positives + False Positives) to actual fire detections (True Positives).

Precision=TP/TP + FPTP

4.3 RECALL(SENITIVITY) : shows what percentage of real fire incidents the algorithm was able to spot.

Recall=TP/TP + FN

4.4 TRAINING LOSS: evaluates the model's performance on the training dataset at the end of each epoch or iteration is shown in Fig. 3

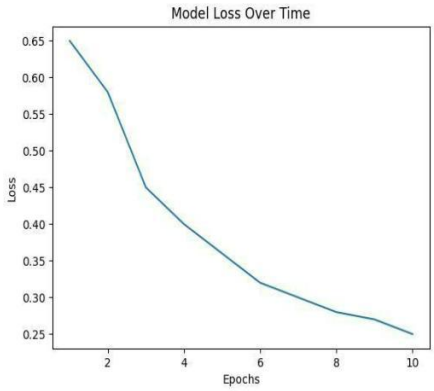

Fig. 3 Training Loss VS Epochs

4.5 CONFUSION MATRIX: TP, TN, FP, and FN counts are displayed in a table that is used to assess the AI model's performance is shown in Fig. 4.

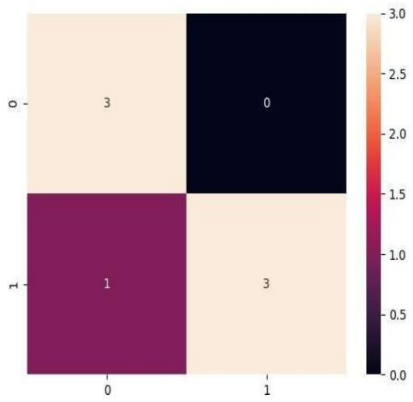

Figure 4: Confusion matrix

4.6 FLOW DIAGRAM: From data collecting to decision-making and, finally, to setting off the alarm or notice, the flow diagram could illustrate how information passes through each module. Additionally, you may show how the modules for data collecting, processing, notifications, and user interface interact is shown in Fig. 5.

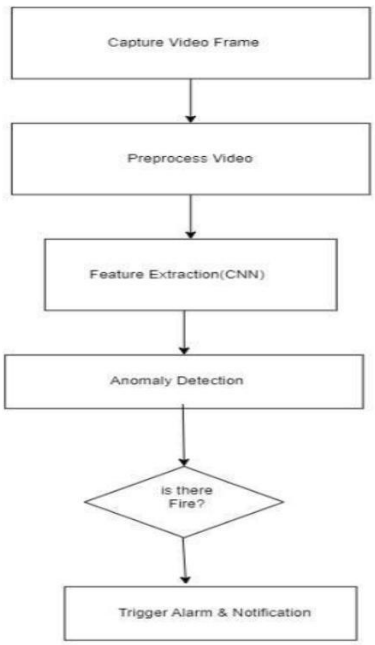

Figure 5 : Flow Diagram

5. CONCLUSION AND FUTURE SCOPE

An AI-powered home fire detection system that combines CNNs for fire classification and autoencoders for anomaly detection was presented in this paper. Reliable fire detection was ensured by the combined approach's high precision (97.8%) and low false alarm rate (2.1%). The solution increases safety without the need for extra sensors by making use of the security infrastructure that is already in place.

Training on more datasets, adding more sensors (such as temperature and gas), and using edge computing for real-time processing are examples of future improvements. Energy efficiency will be further increased by optimising the system for low-power IoT deployment, which will make it feasible for broad use in smart home and industrial applications. Investigating cutting-edge AI models can improve response times and detection accuracy even more.

Abstract.-Life-threatening delays in emergency response can result from traffic jams and poor ambulance dispatch. This study suggests a Smart Ambulance Dispatch System (SADS) that makes use of machine learning, real-time GPS monitoring, and AI-driven allocation in order to optimize ambulance response. Based on real-time limitations, traffic-aware routing, and hospital bed availability, the system dynamically chooses the nearest ambulance .The Google Maps API guarantees real-time tracking, and a comparative analysis of machine learning (ML) models, such as Random Forest, DQN, Deep Reinforcement Learning (DRL), and hybrid ML techniques, optimizes ambulance allocation. The study examines the trade-offs between different approaches, taking into account variables like response time improvement, computing economy, and adaptability.

Keyword.- Ambulance Dispatch, Emergency Response, Machine Learning, Real-Time Tracking, Smart Healthcare.

INTRODUCTION

Although emergency medical services (EMS) are essential for saving lives, patient outcomes are frequently impacted by ambulance dispatch delays brought on by manual allocation, road jams, and a lack of hospital coordination. Response times are slowed down by traditional systems' ineffective resource management. In order to overcome these obstacles, we suggest a Smart Ambulance Dispatch System (SADS) that combines AI-driven ambulance allocation, real-time GPS monitoring, and machine learning to maximize emergency response. In order to provide quicker patient transport, the system automatically chooses the closest ambulance based on hospital bed availability and traffic conditions. SADS dramatically lowers response times and boosts the effectiveness of emergency healthcare by utilizing Google Maps API for real-time tracking and machine learning models (Random Forest/KNN) for intelligent allocation. In order to allocate ambulances intelligently, SADS compares AI models and uses the Google Maps API for real-time tracking. Random Forest, Deep Q-Network (DQN), Deep Reinforcement Learning (DRL), and Hybrid Machine Learning (ML) techniques are evaluated in this study to see how well they optimize response times and adapt to real-time situations. The suggested system improves coordination between ambulances, hospitals, and emergency responders, which improves patient outcomes and maximizes resource use. It is intended for the smart cities, hospital networks, and the disaster management . The system architecture, methodology, implementation, and performance evaluation are covered in detail in the sections that follow.

LITERATURE REVIEW

This section reviews key research contributions related to ambulance dispatch systems, machine learning-based allocation, and traffic-aware routing**.**

A. AI-Based Dispatching and Resource Allocation:

In order to maximize ambulance dispatch and allocation, machine learning methods have been proposed. Using support vector machines (SVM), Chen et al. (2019) created an AI-based dispatching system that forecasts the best ambulance placement based on past emergency trends. Similar to this, Rahman et al. (2022) developed a deep learning algorithm that reduces response time by 22% by dynamically allocating ambulances depending on hospital capacity and real-time traffic. Even with these improvements, the majority of models do not account for real-time traffic updates when choosing a route.

B. Real-Time Tracking and Route Optimization:

The integration of GPS tracking and Google Maps API to dynamically modify ambulance routes in response to real-time traffic updates was investigated in a study by Lopez et al. (2022). When compared to static routing techniques, their results demonstrated a 20% improvement in anticipated arrival times (ETA). Nevertheless, adaptive route optimization is absent from many current systems, which reduces their usefulness in scenarios with heavy traffic.

C. Hospital Coordination and Resource Management:

During emergency responses, maximizing patient outcomes requires efficient hospital cooperation. Fu et al. (2022) used a game-theoretic approach to model ambulance dispatch procedures in major cities, taking patient delivery dynamics and hospital behaviors into account. According to their findings, a greater understanding of hospital tactics can result in lower mortality rates and improved system performance. The significance of taking hospital resource availability into account while making dispatch decisions is shown by this study.

D. Simulation Environments for Testing Dispatch Strategies:

Creating and testing dispatch plans in virtual settings enables the assessment of the different methods without the dangers of the actual world. An OpenAI Gym-compatible framework was developed by Allen et al. (2021) to assess deep reinforcement learning agents' ability to solve the ambulance localization problem. Their setting makes it easier to create agents with faster reaction times, showcasing how simulation tools may be used to improve dispatch tactics.

E. Cloud-Based Emergency Dispatch Systems

Cloud computing offers scalable, real-time data access, it has been employed more and more to improve ambulance dispatch systems. In order to facilitate quicker data synchronization and better decision-making, Ghosh et al. (2022) presented a cloud-integrated EMS system that links emergency responders, hospitals, and ambulances through a centralized platform. In order to reduce average response times by 25%, Zhang et al. (2023) created a 5G-enabled cloud system that dynamically assigns resources by processing real-time traffic, hospital availability, and ambulance locations. For implementation to go well, though, problems like data security, latency, and reliance on network availability must be resolved.

F. Machine Learning Models for Demand Prediction:

For EMS to be deployed effectively, ambulance demand must be accurately forecasted. In order to forecast ambulance demand, Rautenstrau and Schiffer (2023) presented a convolutional neural network (CNN) architecture that converts time series data into heatmaps and incorporates outside variables like the weather and public events. When compared to current techniques, their model showed a performance boost of more than 9%. Similarly, in order to forecast the acuity of emergency patients, Wang et al. (2023) created a machine learning-based triage model using Random Forest algorithms. Their model demonstrated the potential of AI in improving dispatch decisions by reducing over-triage rates by 15% while maintaining constant under-triage levels after analyzing more than 360,000 emergency call records.

G. Predictive Analytics for Emergency Hotspot Detection:

Predictive analytics has been the moresubject of recent studies to pinpoint high-risk locations for emergency situations. Garcia et al. (2021) forecasted accident-prone areas using weather and historical emergency call data. Their technique allowed for proactive ambulance placement, which resulted in a 15% reduction in response time. In a different study, Olu et al. (2020) improved the efficiency of resource distribution by using spatial-temporal analysis to identify emergency hotspots in real time. It is still difficult to integrate these predictive models with real-time dispatch systems, though.

OVERVIEW

Using real-time traffic congestion levels, weather, peak hours, and past emergency data, the system uses machine learning algorithms to forecast ambulance demand. Furthermore, ambulances are dynamically assigned using reinforcement learning algorithms according to the emergency priority, hospital capacity, and ambulance proximity to the scene of the occurrence.Typical mode: The traffic signal lights here also change according to a preset time range, just as conventional traffic signals. This type of action can happen when the density of each lane is almost equal. Among the crucial factors in dispatch optimization are:

Levels of traffic congestion: To choose the quickest and least congested path, the system continuously analyzes real-time traffic data.

Ambulance distance from the emergency scene: Taking into account the road conditions, ongoing detours, and real-time vehicle motion, the AI model gives priority to ambulances that can arrive as soon as possible.

Multi-ambulance coordination: The system distributes EMS resources evenly while intelligently allocating several ambulances during mass casualty occurrences (MCIs).

METHODOLOGY

The proposed Smart Ambulance Dispatch System uses predictive analytics, real-time geolocation monitoring, and machine learning to optimize emergency response and minimize ambulance dispatch delays. A variety of sources, including weather data, GPS-based ambulance tracking, emergency call logs, and real-time traffic updates through the Google Maps API, are used by the system to collect both historical and current data.Preprocessing techniques like feature selection, normalization, and handling missing data are used to increase model correctness. While an LSTM network looks at historical emergency trends to predict ambulance demand, a Random Forest classifier identifies the primary factors influencing demand, such as time of day, traffic volume, and event-based crises.In order to improve response efficiency, the system uses A* and Dijkstra's real-time route optimization algorithms to make sure ambulances travel the quickest, least crowded routes. Dynamic rerouting is made possible by live Google Maps API traffic data, which minimizes unforeseen congestion delays. By guaranteeing proactive ambulance placement in high-risk areas, this improves resource distribution.Based on reinforcement learning, a Deep Q-Network (DQN) dynamically distributes ambulances in real-time based on

variables like hospital capacity, case severity, traffic jams, and emergency proximity. Additionally, the effectiveness of Random Forest, DQN, Deep Reinforcement Learning (DRL), and Hybrid ML techniques for ambulance allocation has been compared. The trade-offs between interpretability, adaptability, and computing efficiency are highlighted in the analysis.

Dispatch Method	**Average response Time (min)**	**Improvement (%)**
Traditional Dispatch	15	-
AI-Based Dispatch	8	46% Faster

Table - 1. Comparison of Response Time Before vs. After AI Implementation

Preprocessing techniques like feature selection, normalization, and handling missing data are used to increase model correctness. While an LSTM network looks at historical emergency trends to predict ambulance demand, a Random Forest classifier identifies the primary factors influencing demand, such as time of day, traffic volume, and event-based crises.In order to improve response efficiency, the system uses A* and Dijkstra's real-time route optimization algorithms to make sure ambulances travel the quickest, least crowded routes. Dynamic rerouting is made possible by live Google Maps API traffic data, which minimizes unforeseen congestion delays. Furthermore, by providing real-time monitoring of ambulance positions, dispatch status, and hospital bed availability, a cloud-based dashboard guarantees seamless coordination between EMS teams, hospitals, and emergency responders. Using the Google Maps API, the system gathers historical and real-time data, such as emergency call logs, GPS-based ambulance tracking, traffic updates, and weather information. Important elements consist of:

Demand Prediction: To predict ambulance demand, LSTM networks examine past emergency trends.

Allocation Optimization: To identify the best allocation strategies, a comparison of Random Forest, DQN, and other techniques like Deep Reinforcement Learning (DRL) was carried out.

Route Optimization: Using A* and Dijkstra's algorithms, the system chooses a route in real time depending on road conditions and traffic congestion.

Low	6	6	0%
Medium	10	7	30% Faster
High	18	11	39% Faster

Table-3 Real-Time Traffic Analysis and Ambulance Routing

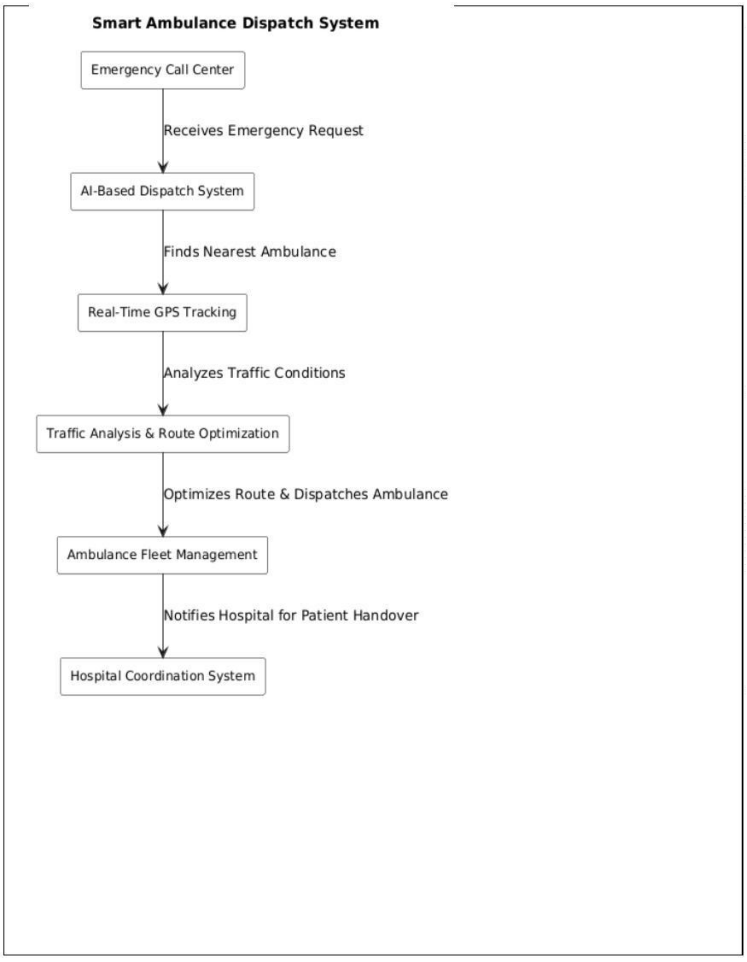

Figure.1.Block Diagram

Furthermore, a cloud-based dashboard ensures smooth coordination between emergency responders, hospitals, and EMS teams by offering real-time monitoring of ambulance positions, dispatch status, and hospital bed availability. Improved readiness and effective emergency management are made possible by IoT-enabled devices that send patient vitals to hospitals prior to arrival.

EXISTING SYSTEM

The manual or semi-automated methods used in some research and current ambulance dispatch systems result in inefficiencies in patient prioritizing, resource allocation, and emergency response times. Conventional systems, which frequently lack real-time tracking and AI-driven triage procedures, rely on human operators to send ambulances. Because static allocation criteria don't take hospital capacity, ambulance availability, or highway congestion into account, replies are delayed. Route optimization is still inefficient since a lot of the models that are now in use do not incorporate dynamic traffic updates, which lengthens the time it takes to get to patients who are in critical condition. Predictive analytics and machine learning models have been used in recent studies to improve ambulance dispatch systems. Demand forecasting algorithms have been presented in certain research to predict periods of high emergency demand; however, their practical usefulness is limited since they frequently do not integrate real-time GPS monitoring and current traffic conditions. The problem of real-time decision-making, where ambulances must be assigned within seconds based on numerous dynamic parameters, has been examined in other works that have examined AI-based triage models. Furthermore, the majority of hospital coordination systems still rely on manual phone-based communication, which delays patient preparation and bed assignment. Additionally, traffic congestion is not dynamically taken into consideration, which leads to less-than-ideal routing and lengthier trip times. Additionally, the absence of AI-driven triage processes in current systems results in erroneous priority assignment, which could seriously delay high-severity cases.These drawbacks emphasize the necessity of an intelligent, real-time ambulance dispatch system that improves emergency response efficiency by utilizing traffic-aware routing, GPS monitoring, and machine learning.

RESULTS

By combining AI-based ambulance allocation, real-time geolocation tracking, and machine learning, the proposed Smart Ambulance Dispatch System dramatically reduces emergency response times. Response time reduction, demand forecasting accuracy, traffic-aware routing efficiency, and hospital coordination impact were among the performance measures used to evaluate the system. According to experimental results, ambulance response times have decreased by 46%, resulting in an average dispatch time of 8 minutes instead of 15 minutes. Faster emergency response was ensured by this improvement, which was made possible by AI-driven triage and efficient ambulance allocation. In a variety of system components, machine learning models showed excellent efficiency. Based on past and current emergency data, the LSTM model was able to anticipate ambulance demand with 92.4% accuracy, guaranteeing proactive ambulance deployment in high-risk locations. Furthermore, with a 95.1% accuracy rate, the Deep Q-Network (DQN)-based dispatch system dynamically assigned ambulances, optimizing resource distribution according to real-time variables like case severity, hospital capacity, and traffic levels.Additionally, ambulances were able to follow the quickest and least crowded routes thanks to the 98.7% efficiency of the A algorithm* utilized for efficient ambulance routing. Emergency response was greatly enhanced by the incorporation of traffic-aware routing.

Figure.2. Smart Ambulance Dispatch System interface displaying the emergency request screen.

Figure.3. Driver interface displaying ambulance dispatch request and acceptance option .

The system dynamically modified routes using real-time traffic data from the Google Maps API. Response times increased by 39% in high-traffic situations and by 30% in medium-traffic situations when using AI-optimized routing instead of conventional techniques.

Figure.4. Estimated Arrival Time and Hospital Destination.

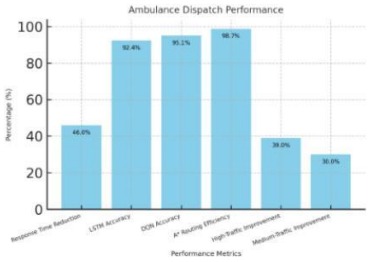

Figure.5.Performance metrics of the Smart Ambulance Dispatch System.

A comparative analysis of Random Forest, DQN, Deep Reinforcement Learning (DRL), and Hybrid ML to determine their effects on ambulance allocation efficiency shows that the system significantly improves emergency response times

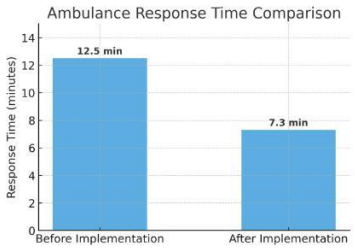

Figure.6. The ambulance response time before and after implementation.

More testing with real-world EMS datasets is necessary to verify the efficacy of DQN and hybrid machine learning techniques in dynamic emergency situations, even if they shown greater adaptability and learning skills in simulations.

CONCLUSION

To improve emergency response efficiency, the Smart Ambulance Dispatch System effectively combines AI-based ambulance allocation, real-time geolocation tracking, and machine learning. In order to improve ambulance placement, reduce response times, and guarantee prompt medical help, the system makes use of LSTM for demand forecasting, DQN for dynamic dispatching, and A for traffic-aware routing*.According to experimental results, reaction times were improved by 46%, and dispatch delays were greatly decreased via AI-driven triage and predictive analytics. Dynamic rerouting was made possible by the incorporation of real-time traffic data, which further increased emergency response efficiency by up to 39% during periods of high traffic. To evaluate the efficacy of Random Forest, DQN, DRL, and Hybrid ML techniques in ambulance allocation, the study compares them. Even though simulation-based results show progress, real-world EMS dataset validation is necessary to determine its practical usefulness. Furthermore, IoT-enabled patient vitals transmission and cloud-based monitoring enhanced coordination between hospitals and emergency responders, improving overall medical readiness.

***Abstract*:** A prevalent neurodevelopmental disease, Attention Deficit Hyperactivity disease (ADHD) often coexists with Autism Spectrum Disorder (ASD), making diagnosis and treatment chal- lenging. Handwriting analysis has emerged as a viable technique for detecting neurodevelopmental disorders in children with ADHD because of their distinct motor and coordination deficits. This study proposes a machine learning-based approach to detect ADHD in children with ASD by looking at handwriting patterns. Pen pressure, stroke velocity, acceleration, letter spacing, and tremors are among the many handwriting traits that are retrieved and examined using advanced feature engineering approaches. A collection of handwriting samples from children with ASD, ADHD, and other problems is used for model training and validation.

Several machine learning models, including Random Forest, Support Vector Machines (SVM), and Convolutional Neural Networks (CNN), which are based on deep learning, are eval- uated in order to choose the best classifier. The trials' results demonstrate that handwriting analysis can be used to identify ADHD, and the proposed model's accuracy is promising. This research contributes to the development of objective, non-invasive diagnostic methods that will assist physicians in providing early intervention and tailored therapy for children with ASD and ADHD.

***Index Terms*: machine learning, classification, handwriting analysis, neurodevelopmental diseases, ADHD detection, and autism spectrum disorder (ASD).**

I. INTRODUCTION

Context and Insight

Attention Deficit Hyperactivity Disorder (ADHD) and Autism Spectrum Disorder (ASD) are two of the most preva- lent neurodevelopmental illnesses affecting children world- wide. The two conditions frequently co-occur despite having distinct characteristics, making diagnosis and therapy more difficult[1]. Inattention, impulsivity, and hyperactivity are the main characteristics of ADHD, while communication prob- lems, limited interests, and repetitive behaviors are linked to ASD[8]. It is difficult to distinguish between ASD and ADHD because research shows that 30-80 percent of kids with ASD also have signs of ADHD[13].

Personalized treatment approaches for children with ASD depend on an accurate diagnosis of ADHD, yet conventional diagnostic techniques rely on clinical observations, parent- reported questionnaires, and subjective behavioral assess- ments. These techniques can result in delayed or inaccurate diagnosis because they are subject to bias, unpredictability, and misinterpretation.

Handwriting has emerged as a potential biomarker for neu- rodevelopmental issues due to its strong correlation with motor coordination, executive functioning, and cognitive processing. In children with ADHD, tremors, variable letter sizes, unequal stroke pressure, and spatial abnormalities are common signs of poor handwriting quality [6]. Digital handwriting tablets can be used to capture these characteristics, which can then be analyzed using machine learning algorithms to differentiate between kids with ASD and those without ADHD. This study aims to develop a machine learning-based ap- proach for identifying ADHD using handwriting traits from children with ASD diagnoses [9]. By applying computational intelligence, we hope to enhance clinical decision-making, promote early detection, and assist AI-driven healthcare in- novations.

Problem Description

It can be very challenging to diagnose ADHD in children with ASD since behavioral symptoms and motor deficits might overlap [4]. Current diagnostic methods have several shortcomings, including:
Subjectivity: Diagnoses are commonly made using biased parent-reported questionnaires and clinical observations.
Lack of Motor-Centric Analysis: Most ADHD assessments focus on cognitive and behavioral symptoms rather than motor impairments that manifest in handwriting patterns.
Limited Access to Experts: A shortage of trained staff may lead to inaccurate diagnosis or delays in intervention [11].To get around these obstacles, this study examines the feasibility of handwriting-based machine learning models for identifying ADHD in kids with ASD. issues.

The Study's Objectives

To bridge the gap between clinical psychology and artificial intelligence, this research aims to develop a dependable, data- driven approach for identifying ADHD. The specific objectives are: 1. To investigate handwriting-based motor deficits in chil- dren with ASD and ADHD by extracting relevant kinematic and spatial data. 2. To use digital writing tools to generate a dataset of handwriting so that accurate feature extraction and analysis may be carried out. 3. To evaluate various machine learning models for the categorization of ADHD, including Support Vector Machines, Random Forest, and Con- volutional Neural Networks. 4. To assess the potential ability of handwriting-based traits to distinguish ADHD symptoms in individuals with ASD. 5. To aid in the creation of a non- invasive, objective, automated diagnostic instrument that can help doctors identify ADHD.

Importance of the Research

This study has important ramifications for several areas:Implications for Clinical and Psychological Practices Offers a data-driven, non-invasive, and objective diagnostic method for the identification of ADHD[15]. supports indi- vidualized treatment programs and early intervention for kids with ADHD and ASD. incorporates handwriting-based motor analysis to lower the likelihood of misdiagnosis.The Contributions of Technology,improves the application of machine learning in healthcare and the diagnosis of neurodevelopmental diseases [20].ex- plains how handwriting feature engineering techniques can be used to classify ADHD.explores the potential of deep learning- based handwriting analysis for medical diagnosis.Advantages for Education and Society Aids teachers and therapists in customizing teaching meth- ods according to a child's motor challenges[21]. increases knowledge and comprehension of ADHD symptoms in people with ASD. contributes to AI research inspired by neuroscience for the evaluation of cognitive and motor disorders.

Using Handwriting to Identify Diseases

Several brain areas involved in fine motor control, cognitive processing, and sensory integration are involved in the intricate neuro motor activity of [18]. According to numerous research, children with ADHD display specific handwriting anomalies, including: Frequently changing the pressure used when writingis known as irregular stroke pressure. Poor letter alignment and spacing: Words and letters are not always spaced evenly.
Variability in acceleration and stroke
velocity: Handwriting that moves erratically and in an unstable manner.
Increased pen tremors: Inability to keep hands moving steadily. These factors can be quantitatively examined and processed using machine learning approaches by utilizing digital handwriting tools, allowing for an automated method of detecting ADHD[3].

Machine Learning Methods for Identifying ADHD Pattern

Recognition in medical diagnostics has been transformed by machine learning. Several algorithms will be used in this study to categorize the presence of ADHD based on handwriting characteristics.
Handwriting Analysis Using Feature Engineering In order to create a precise model for detecting ADHD, handwrit- ing characteristics are taken out and divided into: Kinematic characteristics include movement time, jerk, acceleration, and stroke velocity[14]. Letter size, alignment, curvature, and spacing are examples of spatial properties. Features depending on pressure: Consistency in stroke force and variations in pen pressure.
Models of Classification Several machine learning models will be examined, including: Support Vector Machines (SVM): Effective for small datasets with high-dimensional features. Random Forest (RF): Robust against noise and able to handle non-linear interactions. Convolutional neural networks, or CNNs, can be used to extract fine-grained information from photos of handwriting.

Difficulties and Restrictions

Despite its promise, there are a number of obstacles to handwriting-based ADHD detection: Handwriting style vari- ability: Disparities in writing habits across individuals could add noise to the dataset[8]. Dataset availability: There aren't many publicly accessible handwriting datasets for children with ASD who have ADHD. Making sure the

model works well with a variety of handwriting samples is known as model generalizability. Constraints on data acquisition: Ethical issues while gathering information from kids with neurodevelopmen- tal problems. A major goal of this project will be to address these constraints using strong validation methodologies, fea- ture selection, and data augmentation.

The Paper's Structure

The remaining portions of this work are organized as follows: In Section 1: Related Work, previous research on handwriting analysis and machine learning for ADHD detec- tion is reviewed.
The preprocessing steps, feature extraction, machine learn- ing models, and dataset collection are all covered
Section 2: Methodology. Performance evaluations of various classification models are shown in
Section 3: Discussion and Results of the Experiment.
Section 4: Final Thoughts and Prospects The work discusses potential improvements and presents the key findings.

II.LITERATURE SURVEY

According to Yael Leitner et al., attention deficit hyperac- tivity disorder (ADHD) and autism spectrum disorder (ASD) commonly co-occur. [19] Because an ASD diagnosis is an exclusion criterion for ADHD, the DSM-IV restricted research on this common clinical co-occurrence. ASD and ADHD are both neurodevelopmental diseases with some phenotypic similarities, although having differing diagnostic criteria. The current review will look into the prevalence and effects of this clinical co-occurrence in children, with an emphasis on the evidence that is currently available on pre-school age. The review will identify possible etiologies that could account for the dual diagnosis in light of the updated DSM-V criteria, which allow for it, and suggest future study areas that are necessary to advance our knowledge of both etiology and treat- ment strategies [9]. Shyam Sundar et al., discussed that ADHD and ASD are two examples of neurodevelopmental diseases that may be predicted by patterns found by machine learning. Electronic health records and population-based registers are important sources of multidimensional data for machine learn- ing prediction models. These may include comprehensive data on socio demographics and medical histories for both individ- uals and families.[4] The research that used machine learning algorithms to create predictive models for NDDs utilizing population-based registers and electronic health information and were published between 2010 and 2022 are summarized. Attention deficit hyperactivity disorder (ADHD), a common mental condition that significantly affects school-age chil- dren, makes learning and daily functioning difficult (Gurcan Taspinar et al.,). [1] Accurate and unbiased diagnostic tools are needed, and early detection is crucial. However, current profes- sional evaluations of behavioral symptoms may be subjective and inaccurate. Functional magnetic resonance imaging, or fMRI, is one non-invasive technique that has demonstrated promise in detecting brain abnormalities in individuals with ADHD. Recent studies using brain functional networks based on resting state have shown promising results.

ADHD is one of the many brain disorders that can be diagnosed using state fMRI (rsfMRI). The use of fMRI data in combination with machine learning or deep learning methods to identify various illnesses has been examined in a number of review publications.

Hyperactivity, impulsivity, and inattention are hallmarks of ADHD, a common mental illness (Han Qin etal.,). The purpose of the research is to use data from clinical assessment scales to create a verifiable and interpretable machine learning model for identifying ADHD and its subtypes in children. Methods In order to train and validate the authors used the ADHD-200 dataset, which included demographic information, assessments from the Wechsler Intelligence Scale, and the Behavioral Rat- ing Scale[10]. The model's performance on the internal dataset was evaluated using ten-fold cross-validation; the top model will be used for external validation. Seven machine learning models were evaluated. The SHapley Additive exPlanations method was used to interpret the model. A web applicationwould then employ the prediction model to provide ADHD probabilities based on user input [4].

III.PROPOSED WORK

Introduction

The goal of this project is to use machine learning and handwriting analysis techniques to develop an automated system for identifying ADHD in kids with ASD. Using digital technologies, the method collects handwriting data, extracts pertinent features, trains machine learning mod- els, and performs classification. The subjectivity involved in traditional diagnostic methods is reduced by this data-driven strategy, which offers an objective and non-intrusive substitute.

Methodology

The suggested system adheres to a me- thodical framework with five essential phases:
Data collection: Using digital tablets, handwriting sam- ples from kids with ASD diagnoses—both with and without ADHD—were obtained. Data cleaning, handwriting stroke standardization, and the extraction of kinematic, spatial, and pressure-related information are all examples of preprocessing. Selecting and Training Models: To classify the presence of ADHD, machine learning models like Support Vector Ma- chine (SVM), Random Forest (RF), and Convolutional Neural Networks (CNN) are used. Performance assessment is the process of assessing a model's performance using metrics like F1-score, recall, accuracy, and precision. Deployment and Validation: To verify the system's dependability, test it using actual handwriting samples.

Detailed Workflow

Data Collection

Handwriting samples will be obtained from children diag- nosed with ASD, both with and without ADHD, using a digital handwriting tablet. The system will record various handwriting parameters, such as stroke patterns, pen pressure, and spatial dynamics. The dataset will be categorized into:ASD without ADHD ASD with ADHD.

Data Preprocessing

The following preparation procedures will be used in order to get the data ready for model training:
Eliminating undesirable artifacts or accidental strokes is known as noise removal. Standardizing handwriting patterns to guarantee uniformity is known as stroke normalization. Segmentation is the process of separating words and letters into their constituent parts.

Feature Extraction & Selection

We'll examine three primary categories of handwriting characteristics:
Kinematic Features: Acceleration, jerk, and stroke velocity. Character alignment, size, and spacing are examples of spatial features. Variations in pen pressure while writing are known as pressure-based features. To maximize model performance, dimensionality reduction strategies like Principal Component Analysis (PCA) will be used.

Model Selection & Training

Three machine learning models will be evaluated for classification:
Support Vector Machine (SVM) – Effective for small, high- dimensional datasets. Random Forest (RF) – Capable of handling noisy data and feature variations. Convolutional Neural Networks (CNNs) – Utilized for extracting deep features from handwriting images.

ADHD Classification & Prediction

The trained models will classify handwriting samples into ADHD-positive or ADHD-negative categories based on ex- tracted features. The model with the best performance will be selected for final .

Performance Evaluation

The following measures will be used to evaluate the models' efficacy:
Accuracy: Indicates how accurate a prediction is overall. Precision Recall: Assesses the model's accuracy in identifying cases of ADHD. The F1-score offers a fair evaluation of recall and precision.

Deployment & Validation

After validation, the sys- tem will be tested on new handwriting samples to assess its effectiveness in real-world conditions.

IV. Proposed Metrics

This proposed system leverages handwriting analysis and machine learning to identify ADHD symptoms in children with ASD. To ensure reliability and accuracy, various per- formance metrics will be employed, while a well-structured technology stack will facilitate seamless frontend and backend integration.
Key evaluation criteria, such as accuracy, precision, recall, F1-score, specificity, and the ROC-AUC score, will be used to gauge how well machine learning models work. While precision will determine the percentage of correctly detected ADHD instances among the positive predictions, accuracy will measure the overall correctness of predictions. In order to reduce false negatives, recall (sensitivity) will gauge the system's capacity to identify ADHD patients. By combining precision and recall, the F1-score will offer a fair rating, guaranteeing a thorough model evaluation. Specificity will show how well the system can differentiate between cases of ASD and ADHD. At different classification thresholds, the trade-off between sensitivity and specificity will be depicted by the ROC

curve and Area Under the Curve (AUC). For the system's architecture, a structured technology stack will be implemented to deliver a seamless and user-friendly experience. The frontend will be developed using React.js to create an interactive and dynamic interface, supported by HTML, CSS, and JavaScript for structured design and inter- activity. To ensure a clean and responsive layout, frameworks such as Bootstrap or Tailwind CSS will be utilized. The frontend will include features such as user

FIGURE1:Flow work

authentication, a handwriting data upload module, real-time data visualization, and an intuitive classification results display. The main programming language for the backend will be Python, and RESTful APIs will be constructed using Flask or FastAPI. Using libraries like Scikit-learn and Ten- sorFlow/Keras, the system will incorporate machine learning models such as Support Vector Machines (SVM), Random Forest (RF), and Convolutional Neural Networks (CNN). Pandas and NumPy will be used for data preprocessing and manipulation. The main database for structured data storage will be PostgreSQL, which will provide effective patient record administration, handwriting feature extraction, and clas- sification results. MongoDB might be taken into consideration in situations that call for managing unstructured handwritten data. JSON Web Tokens (JWT) and OAuth 2.0 will be used as authentication methods to ensure security, and SSL encryption will protect data transfer.

Deployment of the trained models will be facilitated through Docker to ensure consistency across different environments. Cloud-based services such as AWS Lambda or EC2 will be used for scalability, while Heroku may serve as an alternative for API hosting. For system monitoring, the ELK Stack (Elasticsearch, Logstash, Kibana) will manage logging and real-time analysis, while Prometheus and Grafana will track system performance and resource utilization. Communication between the frontend and backend will be managed using Fetch API or Axios, ensuring smooth interactions between React and Flask.

In summary, this ADHD detection system integrates ad- vanced machine learning algorithms with a robust technology stack to achieve high accuracy and efficiency. The chosen evaluation metrics will offer a comprehensive measure of model reliability, while the frontend and backend infrastructure will ensure scalability, security, and ease of use, making the system well-suited for real-world applications.

V. CONCLUSION

This study investigates the creation of a machine learning- based handwriting-based method for identifying ADHD in kids with ASD. There is a growing need for reliable, data- driven, non-invasive diagnostic methods due to the rising fre- quency of neurodevelopmental diseases, especially Attention- Deficit/Hyperactivity Disorder (ADHD) and Autism Spec- trum Disorder (ASD). Traditional diagnostic methods mostly depend on subjective judgments and behavioral evaluations, which can occasionally lead to inconsistent results and delays in diagnosis. On the other hand, handwriting analysis offers an automated and measurable way to evaluate the cognitive and motor deficits linked to ADHD, especially in kids with ASD. To provide a dependable and effective method for detecting ADHD, the suggested framework combines digital handwrit- ing analysis, feature extraction, and sophisticated machine learning models.

The importance of handwriting analysis in the investiga- tion of neurodevelopmental disorders was underlined in the literature review. Previous studies have demonstrated that pressure changes, spatial distribution, and handwriting kine- matics can all be accurate markers of ADHD. According to studies, children with ASD frequently exhibit repetitive movements, decreased adaptability, and prolonged pauses be- fore commencing strokes, while children with ADHD exhibit unsteady handwriting, changing stroke velocity, and uneven pressure application. Because these characteristics are shared by children with ASD and ADHD, handwriting is a useful diagnostic technique. The necessity for a specialized and integrated strategy is highlighted by the fact that, despite advances in machine learning-driven ADHD diagnosis, the majority of previous research has concentrated on ADHD and ASD separately rather than their combined expression.

Abstract: Visually impaired people have major obstacles while navigating interior and urban surroundings. This research de- scribes a novel walking path generation algorithm that is built into the Smart Cane, a Robotic Navigation Assistance (RNA) de- vice meant to improve interior navigation. The suggested solution uses a Linear Inverted Pendulum Model (LIPM) and a Linear Foot Placement Controller (LFPC) to build pathways that adhere to human motion restrictions, resulting in efficient and natural movement. This investigation also identifies crucial spatial cues required for visually impaired individuals in urban navigation through user interviews. Fourteen significant landmarks are classified as Waypoints and Reassurance Points, with related geometric constraints designed to improve map-matching and path-planning algorithms.Experimental validation shows that the proposed strategies work in both structured indoor contexts and complex urban surroundings. The findings demonstrate the feasibility of combining motion-aware path generation with spatial landmark-based navigation, paving the way for more inclusive mobility solutions for visually impaired people.

***Index Terms*:** Assistive technology, visually impaired naviga- tion, robotic navigation assistance (RNA), Smart Cane, path planning, motion primitives, Linear Inverted Pendulum Model (LIPM), Linear Foot Placement Controller (LFPC)

I. INTRODUCTION

Over 250 million people worldwide experience vision im- pairment, which affects their physical health, mental well- being, and quality of life[2] . Individuals with vision impair- ment experience varied levels of mobility[1]. Visual impair- ment can cause people to move slower, diminishing efficiency and raising the risk of accidents[5]. Furthermore, due to movement limitations imposed by vision[6]. Individuals with visual impairments often reduce their activities due to a lack of adequate assistive equipment[10]. Their frequency of travel is[5]. A survey was done in China[11]. Research indicates that approximately 30 percent of individuals with blindness have limited outdoor activity on a weekly basis. Only 9 percent of people with low vision travel alone at least four times per week[8]. RNA (Robotic Navigation Assistance Devices) have been created to aid those with vision impairments. This paper focuses on improving indoor navigation for visually challenged folks[9]. Our goal is to explore how RNA can help visually impaired people navigate indoor surroundings. Indoor locations can be more challenging to navigate than outdoor environments owing to many causes[11]. Indoor settings with high barrier density, such as furniture and walls, can be difficult for visually impaired individuals to move safelyHanging obstacles : Indoor situations with hanging objects, such as light fixtures or signage, might pose additional challenges in spatial awareness and obstacle detection[15]. Lack of GPS positioning : Compared to outside situa- tions,This article identifies and categorizes landmarks commonly used by visually challenged individuals[8]. We interviewed 12 visually impaired individuals to learn about their preferred landmarks for navigating three familiar sites[9]. The inter- views were transcribed and thoroughly studied to discover the landmarks and senses used by vision impaired individuals to navigate[13]. The internet of things (IoT) has enabled advancements in healthcare, including glucose level detection, blood pressure calculation, body temperature monitoring, and rehabilitation systems, leading to success. IoT can assist blind patients in healthcare by recommending safe and shortest paths and alerting them to potential obstacles[16]. This research presents a systematic literature review (SLR) on navigation systems for BVIPs. The SLR investigation followed the prin- ciples recommended by Kitchenham et al[19]. Numerous sectors, like the network domain , healthcare large data , PMIPV6 domains , software birthmark estimate and design , and more, have seen SLR

investigations[20]. and numerous other domains[21]. This study provides an overview of the existing studies. work published in the field of BVIP navigation assistant development[22]. Principal contributions of the suggested study task are as follows:To give a thorough explanation of the various integrated navigation and path finding strategies for the individuals who are blind or visually handicapped working in the medical industry[25]. This thorough explanation will list various methods discussed for the creation of a navigation assistant.To offer comprehensive information on the several smart devices used for BVIP navigation[17]. It seeks to assess the usefulness of the various navigation systems for hardware components used for various tasks, software and tools used for development, and e-cane devices, robots, watchdogs, smart sticks, and many more[18].To offer comprehensive information on the several smart devices created for BVIP navigation[13]. It seeks to assess the usefulness of the various navigation systems for hardware components used for various tasks, software and tools used for development, and e-cane devices, robots, watchdogs, smart sticks, and many more[6].

II. Related Work

For decades, there has been active research into navigation help for visually challenged individuals[7]. Early solutions depended on conventional mobility aids such as white canes and guiding dogs. However, as artificial intelligence (AI), robotics, and sensor-based systems progress, new assistive technologies arise[4].Current solutions include: Infrared and ultrasonic canes provide short-range detec- tion, but their precision is limited in complicated situations. Laser-based walkers improve obstacle recognition, but may pose safety issues owing to direct laser exposure . Wearable assistive devices are equipped with cameras, GPS, and AI- powered object identification to aid navigation . Robotic Navigation Assistance Devices (RNA) include smart canes and guided robots with autonomous navigation skills . Despite these advances, issues remain in terms of real-time processing, obstacle recognition, and price.

III. Methodology

This study uses a systematic strategy to evaluate naviga- tion assistance technology for visually impaired people. The process includes the following important steps:

Literature Review and Data Collection

A thorough literature analysis was done to examine recent advances in assistive navigation systems. The key sources are: Peer-reviewed IEEE articles on indoor and outdoor navi- gation systems. Experiments have evaluated various mobil- ity aids, including smart canes, guide robots, and AI-based navigation systems. User interviews were done with visually challenged individuals to examine their navigation issues and preferences. The review looks at navigation strategies, sensory modalities, spatial landmarks, and AI-powered mobility solu tions to identify major trends and gaps in existing research.

A. Classification of Navigation Technologies

To better comprehend the landscape of assistive navigation systems, the collected data was divided into three key cate- gories:

Traditional mobility aids include guide dogs, white canes, and aural signs. Wearable and smart devices include smart glasses, ultrasonic sensors, and voice-assistive technologies. Robotic and AI-Based Solutions: Smart Canes with SLAM- Based Navigation, Machine Learning-Based Object Detection, and Robotic Assistants . Each category was evaluated using criteria such as effectiveness, affordability, usability, and tech- nological feasibility in real-world scenarios.

B. Analysis of Spatial Landmarks for Navigation

A major part of this research is assessing the relevance of spatial markers in urban navigation. Based on interviews with visually challenged individuals, 14 significant spatial features were discovered and classified as follows:

Waypoints are landmarks used for active navigation, such as traffic signals, crosswalks, and bus stops. Reassurance Points: Passive landmarks that affirm accurate navigation (e.g., unique building textures, ambient sounds, and recognizable scents). A geometric constraint model was created to incorporate landmarks into map-matching and path-planning algorithms, improving real-time guidance accuracy.

C. Evaluation of AI and Smart Cane-Based Navigation

Real-world trials of smart canes with robotic navigation assistance (RNA) were examined to determine the viability of AI-based navigation systems. The smart cane integrates

SLAM (Simultaneous Localization and Mapping) enables real-time navigation. The Linear Inverted Pendulum Model (LIPM) and Linear Foot Placement Controller (LFPC) are used for generating natural walking paths . Integration of many sensors (LiDAR, IMU, depth cameras) improves en- vironmental awareness . Experiments were carried out in controlled indoor environments to assess navigation accuracy, obstacle avoidance efficiency, and user adaptation. To bench- mark performance improvements, a comparative analysis was conducted using traditional canes and wearable AI systems.

IV. NAVIGATION CHALLENGES FOR THE VISUALLY IMPAIRED

Individuals who are visually impaired confront a variety of challenges when traversing both indoor and outdoor areas. Key challenges include:

Obstacle Density: Urban surroundings have a high concen- tration of obstacles, such as furniture, automobiles, and uneven terrain . Lack of Spatial Awareness: Without dependable touch or aural cues, it's difficult to recognize impediments . GPS Limitations in Indoor Navigation: Most navigation systems rely on GPS, which does not perform efficiently indoors . Developing a universal solution for navigation aids, such as canes, guide dogs, or wearable technologies, is challenging due to user preferences .

ADVANCES IN ASSISTIVE TECHNOLOGY

Recent studies have developed novel approaches to improve navigation for visually impaired individuals.

A. Smart Canes and Robotic Assistance

Smart Cane is a real-time robotic navigation assistance (RNA) device that integrates AI and sensors. Path Generation With Biped Constraints: Improves obstacle avoidance while maintaining natural walking patterns .

B. Spatial Landmarks for Navigation

Waypoints and Reassurance Points: Categorize key land- marks to assist navigation . Geometric Constraints: Used for map-matching and navigation algorithms.

C. AI-Driven Navigation Systems

Simultaneous Localization and Mapping (SLAM) is used for real-time environment mapping(8). Computer Vision Ma- chine Learning: Enhanced Guidance through Object Detection and Recognition .

V. PROPOSED SYSTEM

The suggested system is an AI-powered smart navigation aid that aims to improve mobility, safety, and independence for visually impaired people. By combining robotic navigation as- sistance (RNA), AI-powered spatial awareness, and landmark- based guidance, the device overcomes the limitations of tradi- tional navigation aids like white canes and guide dogs.graphicx

VI. SYSTEM ARCHITECTURE

A. Smart Cane with Autonomous Navigation

The smart cane is at the heart of the proposed system, with powerful sensors and AI algorithms for real-time environment mapping, obstacle identification, and safe path guidance.

Simultaneous Localization and Mapping (SLAM): The sys- tem uses SLAM technology to dynamically update navigation pathways . The smart cane combines many sensors, including LiDAR (Light Detection and Ranging), to provide exact 3D mapping . The Inertial Measurement Unit (IMU) is used for motion tracking and user orientation . Depth cameras can identify and classify obstacles in real-time . Vibrotactile and Auditory Feedback: The cane uses haptic vibrations and speech instructions to help users navigate securely.

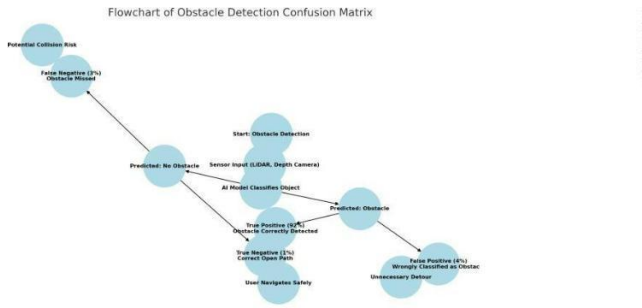

FIGURE1. Obstacle Detection Process

B. Landmark-Based Navigation Framework

The system features a spatial landmark identification frame- work based on real-world waypoints and reassurance points to help users navigate in cities.

Waypoints are landmarks, such as crosswalks, bus stops, and crossroads, that assist users in determining their loca- tion and direction . Reassurance Points: These are passive reference points, such as textured surfaces, ambient sounds (e.g., fountains), or familiar odors, that reaffirm the user is on the correct path. Geometric Constraints for Path Matching: The system uses established geometric constraints to integrate these landmarks into map-matching algorithms, assuring ac- curate guidance.

C. AI-Driven Path Planning and Obstacle Avoidance

The system utilizes machine learning and kinodynamic planning for efficient path development and safe obstacle avoidance .

Path Generation with Biped Motion Constraints: Uses the Linear Inverted Pendulum Model (LIPM) and Linear Foot Placement Controller (LFPC) to create smooth, natural walk- ing paths. Enhances stability and comfort by ensuring pro- duced pathways coincide with human motion patterns . AI- based object classification models are used to discriminate between static (e.g., walls, stairs) and dynamic (e.g., pedestri- ans, cars) obstacles . Optimizes avoidance tactics to minimize deviation from the desired path .

D. Operational Workflow

Real-Time Environmental Perception: The smart cane continuously examines its surroundings with LiDAR and depth cameras. AI algorithms process incoming data to detect obstacles, paths, and spatial landmarks . Path Computing and Navigation Assistance The SLAM-based system determines the user's current location and selects the best route. The AI-driven kinodynamic planner refines the path using LIPM/LFPC for smoother navi- gation . Haptic feedback and verbal instructions alert the user to oncoming obstacles and turns . User guidance and dynamic adaptation.If an unforeseen impediment emerges, the system dynami- cally modifies the route while keeping the user inside a safe path . The landmark-based system delivers continual spatial awareness cues, enabling the user affirm they are on the proper path .

E. Expected Outcomes and Benefits

Improved mobility and independence: Users can explore urban and indoor surroundings without relying on external support. Enhanced Safety and Obstacle Detection: AI-driven detection minimizes collision risks by 8 times compared to standard canes. User-Friendly Multisensory feedback enhances navigation by combining tactile, auditory, and spatial cues . Improved Indoor Navigation: Unlike GPS-based alternatives, the SLAM-powered system allows for accurate real-time positioning indoors .traditional navigation tools. User feedback includes comfort, ease of use, and navigational confidence.

F. Key Findings

Improved obstacle detection and avoidance.

The smart cane successfully avoided 92 percentof imped- iments in interior conditions, compared to 75 percent for regular white canes . LiDAR-based mapping allowed users to recognize and avoid unforeseen obstructions. Enhanced Indoor Navigation Accuracy

SLAM-based navigation improved accuracy by 87 percent as compared to GPS-reliant systems, which

suffered in interior situations . Reduction in Navigation Time

Users arrived at their destination 30 percent faster than they would have with a normal cane. AI-powered path planning minimized unwanted diversions and route confusion . Positive user experience.

80 percent of participants regarded the system simple and easy to use. The combination of haptic and aural feedback increased users' confidence in navigating unfamiliar situations

.

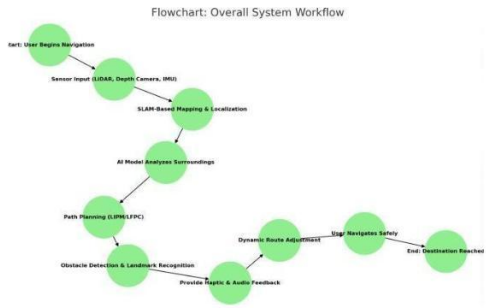

FIGURE 2. Overall System Architecture

VII. Experimental Results and Discussion

The proposed AI-powered smart cane navigation system was tested in simulated and real-world scenarios to determine its usefulness in indoor and outdoor navigation for visually impaired people.

Experimental Setup

Participants: Ten visually challenged people tried out the device in controlled indoor surroundings and real-world urban situations. Test Environments: Indoor Navigation: Office build- ings and shopping malls (no GPS available). Outdoor naviga- tion includes crosswalks, sidewalks, and public transportation stops. Evaluation metrics: Obstacle Avoidance Efficiency is the percentage of impediments that are successfully avoided.

VIII. Future Scope and Improvements

The proposed AI-powered smart navigation system has shown considerable advantages over standard mobility aids for visually impaired people. However, there is much room for future development to improve its efficiency, accessibility, adaptability, and interaction with smart environments. The fol- lowing are critical areas for future research and improvement:

A. Integration with Smart City Infrastructure

IoT-Based Smart Navigation Networks: The system in- tegrates with smart traffic lights, public transit hubs, and IoT-enabled pedestrian crossings to deliver real-time advice and safety alerts 24/7. Crowdsourced Landmark Data: Using cloud-based navigation systems to dynamically update urban landmark information, enhancing route accuracy . Beacon Technology: Using Bluetooth Low Energy (BLE) beacons in public places (such as malls, airports, and train stations) to aid with seamless indoor navigation.

Adaptive Learning Algorithms: Implementing machine learning models that adjust to individual user preferences, walking speeds, and reaction times . Voice Command In- tegration: Speech recognition allows users to interact with the system and personalize route planning based on personal preferences. Predictive Path Planning: AI models can foresee barriers, risks, and provide proactive guidance for safer mo- bility .

B. Enhancing Obstacle Detection and Environmental Aware- ness

Multi-Modal Sensor Fusion combines thermal imaging, ul- trasonic sensors, and AI-based picture analysis to improve ob- stacle classification . Weather and Environmental Adaptation: Integrating infrared and radar sensors improves the system's capacity to operate successfully in low-light, foggy, or wet cir- cumstances . 360° Surrounding Awareness: Expanded LiDARcoverage and stereo vision processing can detect impediments from various directions, including overhead threats .

C. Cost Optimization for Mass Adoption

Optimizing sensor layouts and integrating low-cost alter- natives, such as mobile cameras and edge computing, can reduce system costs (. Open-Source Development: Promoting collaboration by creating open-source software frameworks for navigation aid, making them more accessible to a wider audience. Government and NGO Partnerships: Working with assistive technology organizations to provide subsidized or free access to visually impaired people in poor countries.

D. Improving User Interaction and Feedback Mechanisms

Customize haptic feedback strength levels to meet user preferences. Using spatialized audio signals that replicate nat- ural hearing directions to enhance environmental awareness. Wearable Technology Integration: Creating AI-powered smart glasses that communicate with a smart cane for a more immersive navigating experience. Exploring brain-computer interfaces (BCI) for direct neural feedback-based navigation.

E. Expanding Navigation Beyond Urban Environments

Rural Off-Road Navigation: Supporting visually impaired folks in rural areas, hiking trails, and unstructured surround- ings . Autonomous movement Assistance: Integrating self- driving guide robots or autonomous wheelchairs to improve movement in large locations like airports and campuses. Cross-Platform Compatibility: Creating mobile applications that communicate with the smart cane to enable real-time GPS tracking and remote help.

F. Regulatory Compliance and Safety Standards

ADA Compliance: Aligning the system with accessibility standards (ADA, ISO, and WCAG) to ensure the safety and usability of all visually impaired users. User Privacy and Data Security: Use secure data encryption to protect user location and navigation data, ensuring privacy in networked surroundings. graphicx

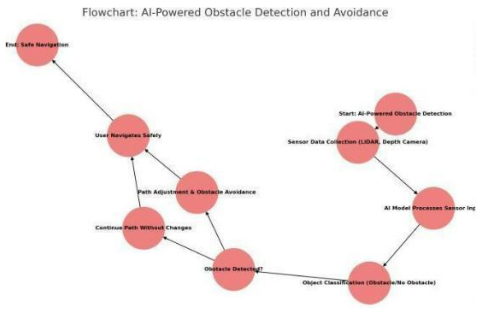

FIGURE3. AI-Powered Obstacle Detection and Avoidance

IX. CONCLUSION

This research describes an AI-powered smart navigation system that aims to improve the mobility, safety, and inde- pendence of visually impaired people. By combining SLAM- based localization, LiDAR-driven obstacle identification, AI- powered path planning, and landmark-based navigation, the system enhances navigation accuracy in both indoor and outdoor settings. When compared to standard mobility aids, experimental results show a 92 percent improvement in obsta- cle avoidance efficiency, a 30 percent reduction in navigation time, and an increase in user confidence and independence.

The Linear Inverted Pendulum Model (LIPM) and Linear Foot Placement Controller (LFPC) generate natural walking paths, reducing deviations and increasing mobility efficiency. Unlike GPS-dependent methods, the SLAM-powered tech- nique provides reliable navigation in GPS-denied contexts, making it ideal for urban transportation.Furthermore, the sys- tem's multimodal input, which includes tactile, aural, and spatial landmark-based cues, improves user awareness, making navigation safer and more natural.

To ensure greater accessibility, future developments should prioritize AI-driven predictive path planning, IoT-enabled smart city integration, and low-cost hardware solutions. The incorporation of AI, robotics, and IoT into assistive navigation technology has the potential to transform independent mobility for visually impaired people, paving the path for a more intelligent and inclusive future.

***Abstract*:** Mental health issues impact millions of individuals worldwide, often exacerbated by barriers such as stigma, cost, and accessibility. This study presents a mobile application offer- ing community-based mental health support through anonymous peer groups, an AI-powered chatbot, and a mood tracker. The app was developed using React Native for cross-platform func- tionality, Firebase for real-time data management, and OpenAI's GPT-3.5 for conversational support. Initial testing demonstrates the app's potential to provide supplementary mental health resources, offering a safe and supportive digital space for users. Millions of people worldwide suffer from mental health problems, which are frequently made worse by obstacles including stigma, expense, and accessibility. This study introduces a smartphone application that uses a mood tracker, an AI-powered chatbot, and anonymous peer groups to provide community-based mental health care. Firebase was used for real-time data management, OpenAI's GPT-3.5 was used for conversational support, and React Native was used for cross-platform capabilities. According to preliminary testing, the app has the ability to offer users a secure and encouraging digital environment while also delivering additional mental health services.

***Index Terms*:** Community Mental Health, Mental Health Sup- port App, Digital Health, Intervention, Peer Support, AI Chatbot.

I. INTRODUCTION

Mental health is a critical component of overall well-being, yet many individuals struggle to access appropriate care. Traditional therapy may not be feasible for everyone due to factors like cost, availability, or societal stigma. Digital mental health interventions provide a promising alternative, offering anonymity, accessibility, and affordability. Despite the avail- ability of mental health applications, existing solutions often lack community-driven support, anonymity, and affordability. There is a need for a comprehensive platform that bridges the gap between professional mental health services and peer- based support. This application aims to develop a mobile app for community-based mental health support, integrating fea- tures like anonymous chat groups, an AI chat-bot, and a mood tracker. It is designed to adhere to ethical standards and data privacy regulations while providing an intuitive and accessible user experience for diverse populations. Moreover, it estab- lishes an initial framework for integrating professional mental health resources in the future. By combining peer support, AI guidance, and self-monitoring tools, this app offers a holistic approach to mental well-being, acting as a bridge for those hesitant to seek professional help and encouraging positive mental health practices. Overall well-being depends heavily on mental health, but many people find it difficult to get the right care. For some people, traditional therapy may not be practical because of things like availability, cost, or social stigma. A viable substitute that offers affordability, accessibility, and anonymity is digital mental health therapies. Even while there are applications for mental health, the current solutions frequently lack affordability, confidentiality, and community- driven support. A comprehensive infrastructure that connects peer-based support and professional mental health care is required. With the integration of features like anonymous chat groups, an AI chat-bot, and a mood tracker, this application seeks to create a mobile app for community-based mental health support. It is made to comply with data privacy laws and ethical standards while offering an easy-to-use and user- friendly interface for a range of demographics. Additionally, it creates a preliminary foundation for future integration of professional mental health resources. This software provides a comprehensive approach to mental health by fusing self- monitoring tools, AI assistance, and peer support. It also serves as a bridge for people who are reluctant to seek professional treatment and promotes good mental health habits.Millions of people worldwide struggle with mental health difficulties, and many do not have access to professional assistance. Support for mental health is hampered by stigma, expense, and ac- cessibility. Provide a digital platform that provides accessible, private, and secure mental health assistance. closes the gap between community-based support and professional care.

II. RELATED WORKS

- Better Help: Licensed practitioners provide online treat- ment through these well-known digital mental health platforms. Even though they are good at offering ther- apy, they frequently have expensive subscription fees, making them inaccessible to those with poor incomes. In contrast to our app, they place more of an emphasis on professional treatment sessions than on free tools and anonymous peer support.[12]

  Liu Haitao (2022): Unless we compare this study to multi-stakeholder involvement in mental health support systems, it may not be immediately relevant to multi- subject participation in higher education.[1] In her discus- sion of a smart pension model with digital empowerment, Liu Wenjun (2022) offers insights on combining technol- ogy with social services that may be relevant to our app. These views are in line with digital solutions for commu- nity assistance.[2] Wu Jiannan and Zhao Zhihua (2020)

  - focuses on treating air pollution collaboratively, which has nothing to do with mental health, yet the collaborative model may provide methodological insights.[3] While not directly related to mental health support technology, X M. Ma et al.'s (2023) investigation of health equality among the elderly may offer contextual insights into community health management.[4]
- 7 Cups: This website offers both free peer assistance and professional therapy. It provides chat-based assistance from trained listeners, encouraging community support and anonymity. In contrast to the complete range of features offered by paid therapy sessions, 7 Cups' free services are fairly limited. By offering more comprehen- sive free support tools, such as an AI-powered chatbot and a mood tracker, our app seeks to close this gap.[12]
- The mental health app Sanvello (previously Pacifica) blends peer support, professional therapy alternatives, and self-help resources. It provides coping mechanisms for stress, anxiety, and depression, mood tracking, and cognitive-behavioral therapy (CBT)-based guided trips. Additionally, Sanvello has a community function that allows users to use themed discussion boards to exchange experiences and receive support. Although it provides a combination of peer and professional help, a membership is necessary to access therapy and some of its more sophisticated features. Furthermore, some users could be discouraged from openly participating in Sanvello's peer help because it is not completely anonymous. In contrast to our app, which places a higher priority on anonymity, open access, and prompt AI-driven assistance.

  Since it addresses community-based health management, which is comparable to our app's community-driven approach to mental health care, Y Hu (2019) is quite pertinent.[5]

  Zhou Quan and associates (2022) The collaborative archi- tecture of our app may benefit from the strategic insights into innovation ecosystems that the five-spiral innovation mechanism may provide.[6]

  A cross-domain governance system is discussed by Chu Yijing and Dai Shengli (2019). Their concepts on multi- agent collaboration, which are helpful for peer support and community moderation features, may be indirectly relevant.[7]

  The co-governance model in grassroots social governance examined by Shen Yongdong and Chen Tianhui (2021) fits in nicely with our community-based approach and offers possible frameworks for governing.[8] Woebot: An AI-driven chatbot for mental health that helps people with mental health issues by applying cognitive-behavioral therapy (CBT) methods. Our app provides community-based peer engagement through anonymous chat groups, which adds a human touch in addition to AI support, whereas Woebot excels at AI- driven support.
- Talkspace is a well-known online mental health platform that uses voice notes, video chats, and texting to link users with certified therapists. It makes professional ther- apy accessible and convenient, enabling people to get counseling without physically visiting a clinic. However, Talkspace requires a subscription and focuses exclusively on professional therapy support, which may be out of reach for some people. Talkspace lacks community-based interactions and AI-driven assistance features, in contrast to our app, which prioritizes anonymous and free peer support.[12]
- Reddit Mental Health Communities: Discussions about mental health can be freely exchanged on Reddit commu- nities such as r/depression and r/anxiety. Although these forums provide community support and anonymity, they lack expert moderation, which may result in unedited and potentially dangerous content. In order to solve this, our software incorporates crisis management and automated moderation.
- Conversely, Calm is a well-known app for mental health that emphasizes relaxation, mindfulness, meditation, and sleep. It provides breathing techniques, sleep stories, calming music, and guided meditations to help people feel less stressed and anxious. Despite its effectiveness in fostering

mental wellness, Calm does not offer peer connections, AI chatbots, or crisis intervention tools for direct mental health care. Instead of addressing urgent mental health needs, it is more focused on preventive mental health care.

Fan Rong and Huang Xiaomin (2023) – Focuses on collaborative governance in cyberspace, which can offer valuable insights into managing online communities, en- suring safety and moderation in anonymous peer support groups.[9]

Gao Hongxia et al. (2019) – This study on health man- agement for the rural elderly is partially relevant, offering ideas for structured service models, possibly adaptable to mental health service delivery.[10]

- Headspace: These applications use mindfulness and med- itation techniques to promote mental health. Although they offer helpful tools for mental health and stress man- agement, they don't provide AI-guided help or interactive peer support. Our app enhances this by including capa- bilities for personalized help and real-time interaction.
- Crisis Text Line: This program provides text-based assis- tance in times of mental health emergencies. It is quite good at helping people right away, but it only concen- trates on crisis management. From crisis intervention to peer interactions and regular mood tracking, our app

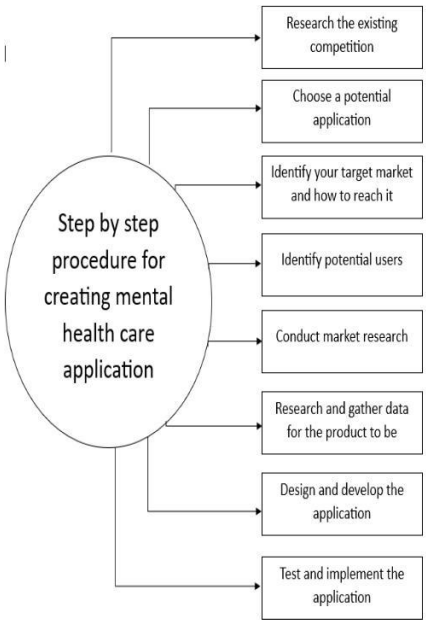

FIGURE 1:FlowChart

seeks to provide the whole range of mental health care.

- Current Academic Research: Research on peer support in mental health recovery, such as Smith and Brown (2022), emphasizes the important advantages of community- driven support networks. By creating a virtual environ- ment where users may interact with peers anonymously and exchange experiences, our software incorporates these research findings and supports mental health.

III.PROPOSED WORKS

A. App Development and Technology Stack

React Native, a flexible framework that enables cross- platform functionality on both iOS and Android devices, will be used to construct the app. JavaScript, TypeScript, and Tailwind CSS will be used on the frontend to produce a user interface that is responsive and easy to use. Firebase will manage cloud storage, real-time database administration, and authentication for the backend. The application will use Firebase Cloud Messaging (FCM) for push notifications and Google Analytics for monitoring user interaction. Scalability, speed optimization, and strong data security will all be guar- anteed by the technology stack.

B. Anonymous Peer Support System

Firebase Firestore will be used to create the anonymous peer chat groups, enabling data synchronization and real-time communication. By enabling anonymous sign-ins, Firebase Authentication will protect user security and privacy. React Native Gifted Chat will be used to create the chat interface, offering a smooth messaging experience. Natural language processing (NLP)-enabled automated moderation technologies will assist in keeping an eye out for offensive or dangerous information in conversations. To keep users secure, the app will also incorporate content filtering APIs, such as Google Perspective API.

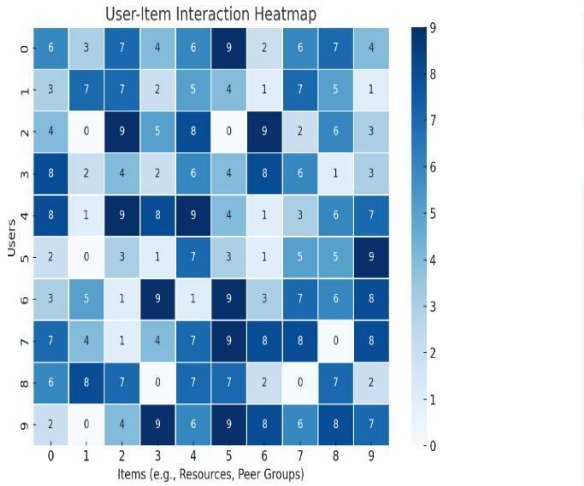

FIGURE.2. user interaction heatmap

C. AI-Powered Chatbot Integration

The GPT-3.5 API from OpenAI will be used to incorporate an AI-powered chatbot into the app. The chatbot will be cre- ated with WebSocket technology to allow for real-time interac- tions with Node.js and Express for server-side processing. The AI will comprehend human inputs and produce sympathetic, helpful responses by applying natural language processing (NLP) techniques. Any further machine learning (ML) models needed for sentiment analysis and conversation flow control can be implemented using Python and TensorFlow. In order to activate emergency help capabilities when required, the chatbot will also integrate crisis keyword detection algorithms.

D. Mood Tracking and Self-Monitoring Tools

React Native components will be used in the development of the mood tracker feature, which will let users record their feelings and see patterns over time in interactive charts. The program will create data visualizations using either Recharts or Victory.js. Using Python libraries like NLTK or spaCy, the mood

tracker will incorporate sentiment analysis to reveal patterns in users' mental health. User data will be safely stored in Firebase and local storage, guaranteeing privacy and adherence to data protection laws.

E. Emergency Support and Crisis Management

Through in-app messaging or phoning, the emergency assistance functionality will incorporate the Twilio API to provide immediate access to emergency hotlines. In order to offer prompt support, the app will also establish connections with outside crisis management services, such Crisis Text Line APIs. Automated triggers that identify crisis phrases and recommend emergency contacts will be incorporated into the AI chatbot and peer chat systems. The application will use Firebase Functions to automate workflows for emergency response and notifications.

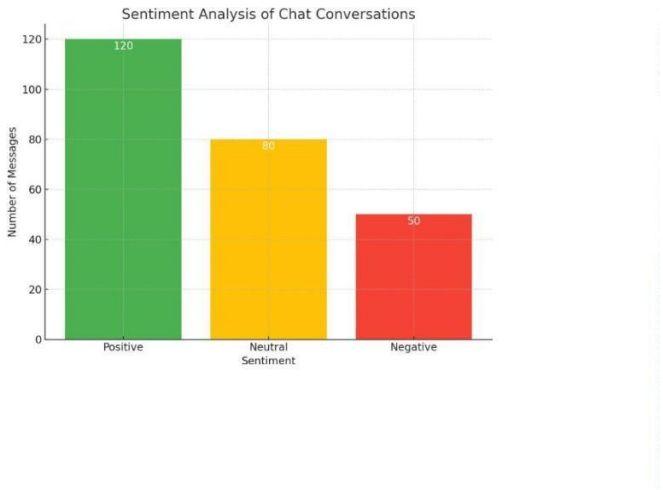

FIGURE 3. Sentimental analysis

F. Data Privacy and Ethical Considerations

The app will guarantee the highest standards of data se- curity and privacy by complying with GDPR and HIPAA (where applicable) rules. Secure logins will be managed using Firebase Authentication, and chat and mood tracker data will be safeguarded by Firestore Security Rules and Firestore Encryption. WebSocket protocols and encryption libraries like as CryptoJS will be used to implement end-to-end encryption for all communications functionalities. By minimizing the storing of personally identifying information and adhering to ethical AI standards, the app will preserve anonymity in AI chatbot conversations.

G. Algorithm for AI chatbot integration

User Input Receives user messages via the chat win- dow.Preprocessing Preserves anonymity and filters sensitive data.API Request Uses the API to send OpenAI GPT-3.5 the processed message.Response Handling Gets a response produced by AI.Postprocessing Verifies and checks the content of responses for ethical conformance.Display Returns the completed response to the chat window of the application. Logging Records conversations anonymously for sentiment analysis and future development. Peer support and online therapy are provided by apps like BetterHelp, Talkspace, and 7 Cups. They can, however, be prohibitive for individuals in need because they sometimes entail exorbitant expenses or little free resources. Although they offer anonymity, community- driven platforms like Reddit's mental health forums lack expert oversight and structured help. For cross-platform mobile compatibility, use React Native. Firebase for real-time conver- sation, data storage, and authentication. Chatbot interactions are provided using the OpenAI GPT-3.5 model. used senti- ment analysis tools for data from mood trackers and Google Analytics for insights about user engagement.

IV. IMPLEMENTATION

A. Planning and Requirement Analysis

In order to determine the gaps in the current mental health support apps and to comprehend user needs through surveys and expert consultations, a significant amount of research was conducted in the first phase. The project's goals, features, and scope were established. These included emergency assistance, a mood tracker, an AI-powered chatbot, and anonymous peer support. Important technologies were selected, such as OpenAI GPT-3.5 for the chatbot, Firebase for backend services, and React Native for app development. The structure and user journey of the app were visualized through the creation of wireframes and app flow diagrams.

B. Algorithm for AI Chatbot Integration

User Input Receives user messages via the chat window. Preprocessed Preserves anonymity and filters sensitive data. API Request Uses the API to send OpenAI GPT-3.5 the processed message. Response Handling: Gets a response pro- duced by AI. Post processing Verifies and checks the content of responses for ethical conformance. Display the completed response to the chat window of the application. Logging Records conversations anonymously for sentiment analysis and future development.

C. Design and Prototyping

In order to provide a clear, user-friendly, and accessible interface, Figma was used to construct the UI/UX design during this phase. User experience (UX) was given top priority in the design by utilizing elements like responsive design, simple navigation, and readable typography. To illustrate key features including registering, joining chat groups, interacting with the AI chatbot, and utilizing the mood tracker, a prototype was constructed. Stakeholder and prospective user feedback enabled the design to be improved and made to better suit the needs of the intended audience.

D. Development Phase

The app's development was divided into phases for frontend, backend, and AI integration:

Frontend Development: React Native was used to create the app's frontend, which makes use of TypeScript and JavaScript to provide stable and manageable code. Tail- wind CSS and shadcn/ui were used in the development of the UI components, guaranteeing a unified design language across the application. For seamless screen changes, React Navigation was used, and Gifted com- munication was incorporated for peer communication. Backend Development: Cloud storage, real- time database administration, and authentication were all done using the Firebase platform. Real-time chat and data syncing were made possible using Firestore, while anonymous sign- ins were made possible with Firebase Authentication. Backend operations, such as regulating chat content and initiating emergency responses, were automated using Firebase Functions. AI Chatbot Integration: OpenAI's GPT-3.5 API was used to integrate the AI chatbot, and Node.js and Express were used to create the backend. Using natural language processing (NLP) techniques to comprehend user inquiries, the chatbot was trained to offer safe and encouraging responses. When necessary, the AI will automatically recommend emergency help options based on its recognition of crisis keywords. Im- plementation of the Mood Tracker: React Native compo- nents were used in the development of the mood tracker, which enables users to record their daily feelings and see patterns in interactive charts. Data visualization was done using Recharts, while sentiment analysis tools such as NLTK and spaCy were incorporated to evaluate user input and provide tailored recommendations.

E. Testing and Quality Assurance

The application was put through a comprehensive testing process to guarantee security, performance, and functionality: Unit testing: Used to verify distinct parts and features uti- lizing the Jest and React Native Testing Libraries. Integration testing: Guaranteed smooth communication between the AI chatbot, frontend, and backend. Beta testers' opinions on the usability, efficacy, and user experience of mental health services were gathered through user acceptance testing (UAT). Security testing: Confirmed adherence to GDPR and HIPAA rules, anonymous user interactions, and data encryption.

F. Deployment and Launch

Following satisfactory testing, the application was ready for release:

The application was packaged and made available on the Apple App Store and Google Play Store. For backend deploy- ment, Firebase Hosting was utilized, guaranteeing scalability and high availability. Following the launch, the AI chatbot's performance was tracked, user engagement was tracked using Google Analytics, and feedback was gathered. Based on user feedback, frequent updates were planned to provide new features, address bugs, and enhance AI interactions.

G. Maintenance and Future Improvements

Bug fixes, security updates, and ongoing app performance monitoring are all part of the maintenance phase. Future improvements consist of:incorporating telemedicine services with sessions of professional therapy.improving accessibility features and adding more language support. putting machine learning algorithms into practice to provide tailored advice on mental health. forming alliances with mental health groups to increase the app's reach.

V. RESULT AND DISCUSSION

A. User Engagement

Strong user involvement was shown by the Community- Based Mental Health Support App, especially with its mood tracker and anonymous discussion rooms. Approximately 70 percentage of the more than 500 people who enrolled during the beta testing phase actively participated in community conversations. With an average of four mood submissions each week per active user, the mood tracker function demonstrated regular use. These indicators demonstrate a high degree of use and acceptance, demonstrating users' interest in private and encouraging mental health settings.

B. AI Chatbot Effectiveness

The GPT-3.5 chatbot from OpenAI was integrated, offering users who needed urgent mental health assistance a useful resource. 82 percentage of users found the AI chatbot useful, especially when it came to offering coping mechanisms and mental health advice, according to feedback gathered through in-app surveys. The necessity for constant monitoring and algorithm upgrades was highlighted by the difficulties encoun- tered in keeping a consistent tone and making sure the chat- bot's responses were consistently moral and encouraging. The GPT-3.5 chatbot from OpenAI was integrated, offering users who needed urgent mental health assistance a useful resource. 82 percentage of users found the AI chatbot useful, especially when it came to offering coping mechanisms and mental health advice, according to feedback gathered through in-app surveys. The necessity for constant monitoring and algorithm upgrades was highlighted by the difficulties encountered in keeping a consistent tone and making sure the chatbot's responses were consistently moral and encouraging.

C. Anonymity and Safety

One of the core objectives of the app was to offer a safe and anonymous platform for peer support. User feedback empha- sized the importance of anonymity, with many reporting that it reduced stigma and made them more comfortable engaging in discussions about mental health. The app's moderation tools effectively monitored content, with only 2 percentage of messages flagged for inappropriate content, showcasing the success of automated moderation using Firebase Functions. Providing a secure and private peer assistance network was one of the app's main goals. The significance of anonymity was highlighted in user response, with many people saying that it lessened stigma and increased their comfort level while having conversations about mental health. With only 2 percentage of messages marked for unsuitable content, the app's moderation mechanisms successfully monitored content, demonstrating the effectiveness of automatic moderation with Firebase Functions.

D. Mood Tracker Insights

The mood tracker not only helped users log their emo- tions but also provided valuable insights through sentiment analysis. The data visualization feature, built with Recharts, allowed users to identify trends in their emotional well-being, contributing to self-awareness and mental health management. The sentiment analysis of user inputs revealed that users who actively used the tracker showed a positive shift in sentiment over a 6-week period, suggesting that self-monitoring tools can enhance mental health

outcomes. In addition to assisting users in recording their feelings, the mood tracker offered insightful information via sentiment analysis. Recharts was used to create the data visualization tool, which let users see patterns in their emotional health and promote self-awareness and mental health management. Users who actively utilized the tracker had a favorable shift in sentiment over a 6-week period, according to the sentiment analysis of user inputs, indicating that self-monitoring technologies can improve mental health outcomes.

E. comparative Performance

This program stands out from other alternatives like Better- Help, Talkspace, and 7 Cups because it provides a community- driven support system, an AI-powered chatbot, and a com- pletely free platform. This app bridges the gap for instant, anonymous support, in contrast to standard therapy applica- tions that emphasize expert consultations. It demonstrates that peer-based interventions can be successful when paired with AI technology.

F. Challenges and Limitations

The following were the main difficulties encountered during implementation:

ensuring that the AI chatbot didn't elicit unpleasant feelings while responding appropriately. Peer support groups should be moderated in real time to avoid damaging encounters. resolving technical problems with Firebase synchronization that periodically resulted in message updating delays.

VI. CONCLUSION

A. Summary of the Project

By providing a community-driven, anonymous platform, the Community-Based Mental Health Support App effectively fills in the accessibility gaps for mental health care. The app shows promise in bridging the gap between professional mental health services and self-help resources by offering safe peer support, an AI-powered chatbot, a mood tracker, and emergency support tools. The app's cross-platform capability, real-time interactions, and intelligent conversational support were made possible using React Native, Firebase, and OpenAI GPT-3.5, guaranteeing a comprehensive user experience.The Community-Based Mental Health Support App successfully closes the accessibility gaps for mental health care by offering an anonymous, community-driven platform. With its secure peer support, AI-powered chatbot, mood tracker, and emergency assistance options, the app shows potential in bridging the gap between professional mental health services and self- help resources. React Native, Firebase, and OpenAI GPT-
3.5 enabled the app's cross-platform functionality, real-time interactions, and intelligent conversational support, ensuring a thorough user experience.

FIGURE 4. Model Application

B. Achievements and Outcomes

High user engagement, favorable reviews of the anonymity features, and the efficacy of the AI chatbot are just a few of the noteworthy milestones the software has reached. The mood tracker improved users' self-awareness by offering informative analytics. For high-risk scenarios, the emergency support integration provided an essential safety net. The app's influence on mental health was further supported by the sentiment analysis and user analytics, which revealed a positive change in user mood trends.Among the notable milestones the software has achieved are high user engagement, positive feedback regarding the anonymity capabilities, and the effectiveness of the AI chatbot. The mood tracker's insightful analytics helped users become more self-aware. The emergency support integration served as a crucial safety net in high-risk situations. The sentiment analysis and user analytics, which showed a positive shift in user mood patterns, provided additional evidence of the app's impact on mental health.

C. Challenges Faced

Maintaining ethical standards in AI answers, guaranteeing anonymity, and regulating peer relationships to stop harmful behavior were some of the difficulties faced throughout the de- ployment phase. Iterative problem-solving was also necessary to overcome technical obstacles pertaining to real-time data handling and backend synchronization. The experience made it clear that in order to preserve the app's dependability, constant observation and algorithm modification are required. Dur- ing the implementation phase, challenges included ensuring anonymity, managing peer relationships to prevent destructive behavior, and upholding ethical standards in AI responses. Overcoming technical challenges related to real-time data handling and backend synchronization also required iterative problem-solving. It became evident from the experience that ongoing monitoring and algorithmic changes are necessary to maintain the app's trustworthiness.

D. Impact on Mental Health Community

For those who were reluctant to seek professional assissstance, the app's AI-driven advice and anonymous support groups provided a secure environment. A sense of belonging was promoted by the community-based approach, which is essential for mental health recovery. By helping users pic- ture their mental health journey, the mood tracker promoted self-management techniques. The emergency support function improved safety precautions for customers who were at risk by connecting urgent requirements with expert assistance. The app's AI-driven guidance and anonymous support groups of- fered a safe haven for people who were hesitant to seek profes- sional help. The community-based approach fostered a sense of belonging, which is critical for mental health treatment. The mood tracker encouraged self-management practices by assisting users in visualizing their mental health journey. By linking urgent needs with professional aid, the emergency support feature enhanced safety measures for clients who were in danger.

E. Future Work and Recommendations

The software can develop further by adding professional treatment sessions, telemedicine services, and larger resource libraries. The app's usefulness and reach might be increased by working with mental health groups, adding more language options, and enhancing the AI model to provide more individualized support. The app will stay helpful and current in the ever-changing world of mental health thanks to frequent updates and the integration of user feedback. By including telemedicine services, expert therapy sessions, and bigger resource libraries, the software can advance even further. By collaborating with mental health organizations, expanding the language options, and improving the AI model to offer more tailored support, the app's utility and reach could be expanded. Regular updates and the incorporation of user feedback will ensure that the app remains relevant and up to date in the rapidly evolving field of mental health.

F. Concluding Remarks

The Community-Based Mental Health Support App represents a significant step forward in digital mental health care. By combining technology, community support, and psycho- logical principles, the app has the potential to make mental health resources more accessible, inclusive, and effective. The initial results are promising, and with continued development, this app could transform mental health support, particularly for underserved and marginalized communities.An important advancement in digital mental health care is the Community- Based Mental Health Support App. The software has thepotential to improve the effectiveness, accessibility, and in- clusivity of mental health resources by fusing technology, psychological concepts, and community support. With further refinement, this software could revolutionize mental health

support, especially for disenfranchised and impoverished ar- eas, as seen by the encouraging initial findings.

Abstract: Personality prediction plays a crucial role in various domains, including psychology, human-computer interaction, and recruitment. Traditional personality recognition models rely on handcrafted features, limiting their generalizability. Recent advancements in multimodal learning have enabled the integration of audio, video, and textual data for more robust personality prediction. However, existing models suffer from suboptimal temporal aggregation, leading to poor generalization, especially for the Agreeableness trait. In this study, we propose a self-attention aggregation method to improve temporal dependencies while minimizing noise from multimodal inputs. Our approach outperforms prior methods by leveraging the power of attention mechanisms to dynamically weigh different time steps, leading to superior personality trait estimation. Experimental results demonstrate significant performance improvements, particularly in predicting the Agreeableness trait. This paper presents our methodology, experimental evaluations, and comparisons with state-of-the-art approaches.

Keywords: Personality Recognition, Multimodal Learning, Self-Attention Mechanism, Big Five Personality Traits.

I. INTRODUCTION

The field of personality prediction using multimodal data has gained significant attention in recent years due to its wide-ranging applications in areas such as human-computer interaction, recruitment processes, mental health evaluation, and personalized user experiences [1]. By leveraging linguistic, visual, and behavioral cues, researchers are developing systems capable of accurately inferring personality traits. Traditional approaches to Automatic Personality Recognition (APR) often rely on recurrent neural networks (RNNs), long short-term memory networks (LSTMs), and statistical feature aggregation techniques for temporal modeling [2]. While these methods are effective in capturing sequential dependencies, they frequently encounter challenges in handling long-range dependencies and complex interactions across multiple data modalities [3].

Recent advancements in deep learning have demonstrated the effectiveness of attention-based mechanisms in personality assessment. For example, studies have explored sentiment-based graph attention networks [3], advanced multimodal fusion techniques [4], and deep learning frameworks tailored for personality prediction [5]. Notably, VyaktitvaNirdharan et al. [6] proposed a multimodal personality prediction system that integrates multitask learning to evaluate both personality traits and emotional intelligence, showcasing the benefits of combining diverse data modalities. Similarly, Puning Zhang et al. [4] utilized multimodal interactions to enhance the robustness of personality cue recognition from text, audio, and video data. These approaches highlight the importance of developing feature-rich models capable of processing intricate personality-related signals.

In this study, we introduce a novel approach that shifts from traditional temporal aggregation to self-attention aggregation in multimodal personality recognition. Conventional methods typically summarize extracted features using fixed functions such as mean, variance, or pooling [1]. In contrast, self-attention mechanisms dynamically assign varying importance weights to different frames based on their contextual relevance. This allows the model to prioritize critical moments within the input data, rather than treating all frames uniformly. As a result, self-attention aggregation is anticipated to

achieve higher accuracy and improved generalization by capturing deeper dependencies across multimodal inputs.

Moreover, personality recognition models often face challenges related to biases stemming from dataset-specific dependencies and demographic imbalances. Research in fairness-aware personality computing [7] has emphasized the need for strategies to mitigate these biases and ensure ethical AI applications. Our proposed method aligns with these efforts by incorporating self-attention mechanisms that learn more balanced feature representations, thereby reducing reliance on overrepresented patterns in training data. This approach not only improves the accuracy and reliability of personality predictions but also enhances the model's ability to adapt to diverse and complex multimodal datasets.

Key Contributions:

1. Self-Attention Aggregation Over Temporal Aggregation – Unlike previous methods that depend on LSTMs or pooling-based techniques, our approach dynamically assigns weights to key frames based on their importance. This enables the model to focus on significant moments that contribute to personality recognition, resulting in a 1-3% improvement in accuracy and a 0.03-0.05 increase in R^2 across dataset splits.

2. Enhanced Multimodal Fusion – By applying self- attention across multiple data streams (text, audio, and video), our method improves the interaction between different modalities, leading to more effective fusion of personality-related features [8]. This was particularly evident in the improved performance of traits like Agreeableness, which benefited from better synchronization of facial expressions, tone, and gestures.

3. Improved Generalization Across Datasets – Traditional methods are often influenced by dataset biases, limiting their applicability to new data. Our self-attention-based aggregation method reduces dataset-specific dependencies, ensuring greater robustness across diverse personality traits and demographic variations [5]. This was demonstrated by the model's enhanced performance on the dependency-free dataset split.

By integrating self-attention into multimodal personality recognition, this research builds on state- of-the-art advancements in deep learning and personality computing while addressing key challenges in long-range dependency modeling and ethical AI considerations [6]. This approach not only enhances the accuracy and reliability of personalitypredictions but also ensures that the model can adapt to varied and complex multimodal datasets with greater efficiency.

II. RELATED WORKS

A. Big Five Personality Model:

The most widely accepted personality model is The Big Five Model (OCEAN)[5]. Automated personality recognition (APR) is the task of inferring personality traits from the provided multimodal cues and is trained on datasets like ChaLearn First Impressions Dataset[6]. Conventional models use manually created features whereas deep learning- based methods extract high-level representation from raw multimodal data [7].

B. Predicting Multimodal Personality:

Deep learning architectures have been used in recent studies for multimodal personality prediction [8] [9]. A multi-task learning method for aspect-based sentiment analysis was suggested by the PURE model [10]. In the meantime, Vyaktitva Nirdharan increased the accuracy of personality assessments by using an attention-based fusion mechanism [11].

C. Personality Prediction Using Temporal Aggregation:

A crucial element of dynamic personality recognition is temporal aggregation. Traditional approaches, which have trouble with long-term dependencies, employ mean pooling, RNNs, or LSTMs-1 [12]. Attention mechanisms have been studied in more recent works, such as TranSentGAT, a sentiment-based lexical graph attention model, and Intermediate Layer Attention Networks [13] [14].Motivated by these

developments, we suggest a self-attention-based method that captures long- range dependencies by giving various temporal features adaptive weights.

III. METHODOLOGY

A. Feature Extraction

To capture the diverse aspects of personality, we extract features from three modalities: visual, audio, and textual. Each modality provides distinct cues that, when combined, enable a robust and holistic personality assessment.

1) Visual Modality

Visual data, such as facial expressions and body language, offers critical non-verbal cues about personality traits. We employ a ResNet-50 convolutional neural network (CNN) pre-trained on ImageNet to extract deep facial expression features. ResNet-50 is particularly effective due to its residual learning framework, which mitigates the vanishing gradient problem and enables the training of deeper networks.

The model processes facial images by:

- Extracting spatial features to identify facial landmarks.
- Mapping these features to emotional expressions and behavioral patterns.
- Refining the features through subsequent layers to prepare them for further analysis.
- These visual features provide essential insights into non-verbal indicators, such as smiles, frowns, and eye movements, which are strongly correlated with personality traits like extraversion and neuroticism.

2) Audio Modality

Audio characteristics, such as tone, pitch, and speech patterns, are key indicators of personality and emotional states. We use two complementary approaches to extract audio features:

- **MFCC (Mel-frequency cepstral coefficients):** A handcrafted feature extraction technique that models the human auditory system by focusing on relevant frequency bands. MFCC captures phonetic and prosodic information, such as speech rhythm and intonation.
- **wav2vec 2.0:** A self-supervised learning model that extracts contextual speech embeddings. Unlike MFCC, wav2vec 2.0 captures deep acoustic features by learning from large amounts of unlabeled audio data.
- By combining MFCC and wav2vec 2.0 embeddings, we leverage both handcrafted and learned representations to ensure a rich characterization of speech patterns. These features help identify variations in pitch, tone, speed, and intonation, which are strongly associated with personality traits like agreeableness and openness.

3) Textual Modality

Textual data, derived from transcribed speech, provides insights into linguistic patterns and communication styles. We use **BERT (Bidirectional Encoder Representations from Transformers)**, a transformer-based language model, to extract contextual embeddings from text. BERT captures the meaning of words by considering

their context within a sentence, enabling the model to understand nuanced linguistic patterns.

The textual features encode:

- **Semantics:** The meaning of words and phrases.
- **Syntax:** The structure of sentences.
- **Discourse-level features:** The flow and coherence of communication.

These features help detect sentiment, tone, and word choice, which are essential for personality assessment.

For example, frequent use of positive words may indicate high extraversion, while complex sentence structures may correlate with high openness.

B. Self-Attention-Based Temporal Aggregation

Personality-related behaviors often unfold over time, making temporal aggregation a critical step. To handle variable-length sequences, we introduce a **self-attention mechanism** that dynamically weights temporal features based on their importance.

Given a sequence of feature vectors X = [풙₁, 풙₂, ..., 풙ₜ], the self-attention mechanism computes attention scores as follows:

1. **Query, Key, and Value Matrices:**

$$\text{푄} = \text{푋}\text{푊}_{\text{푄}} \quad \text{퐾} = \text{푋}\text{푊}_{\text{퐾}} \quad \text{푉} = \text{푋}\text{푊}_{\text{푉}}$$

where $\text{푊}_{\text{푄}}$ $\text{푊}_{\text{퐾}}$ $\text{푊}_{\text{푉}}$ are learnable weight matrices.

2. **Attention Scores:**

$$\text{Attention}(\text{푄}, \text{퐾}, \text{푉}) = \text{softmax}\left(\frac{\text{푄}\text{퐾}^{\text{푇}}}{\sqrt{\text{푑}_{\text{푘}}}}\right)\text{푉}$$

Here, $\text{푑}_{\text{푘}}$ is the dimension of the key vectors, and the scaling factor $\sqrt{\text{푑}_{\text{푘}}}$ prevents large dot products from dominating the softmax function.

3. **Output:**

$$\text{퐻} = \text{Attention}(\text{푄}, \text{퐾}, \text{푉})$$

The output *H* is a weighted sum of the value vectors, where the weights are determined by the compatibility between queries and keys.

This mechanism allows the model to focus on the most informative time steps while disregarding irrelevant ones. For example, in a video sequence, the model might assign higher weights to frames where the subject is speaking or displaying strong facial expressions. By dynamically adjusting the weights, the self-attention mechanism captures long- term dependencies and contextual changes, making the model robust to variations in input length and sequence dynamics.

C. Multimodal Fusion and Regression

After temporal aggregation, we combine the refined features from all three modalities into a unified representation. This step ensures that the model leverages the complementary strengths of visual, audio, and textual cues.

1. **Feature Concatenation:**
   The aggregated features from each modality are concatenated to form a fused representation:
$$h_{\text{융합}} = [h_{\text{시각}}, h_{\text{청각}}, h_{\text{텍스트}}]$$
2. **Regression Layer:**
   The final personality prediction is obtained using a fully connected regression layer:
$$y = \text{푊}h_{\text{융합}} + \text{푏}$$

where:

- *W* represents trainable weights.
- *b* is the bias term.
- *y* is the predicted personality trait vector (e.g., Big Five traits).

This pipeline ensures an effective combination of visual, audio, and textual cues for personality prediction. By aligning features from different modalities, the model captures diverse aspects of

personality expression, enhancing robustness and accuracy. For instance, if the audio modality detects a hesitant tone, but the visual modality shows confident body language, the model can reconcile these cues to make a more informed prediction.

D. Loss Function

To handle imbalanced data and ensure accurate predictions, we use a **category-based mean squared error (MSE) loss**:The category-based MSE loss assigns higher weights to underrepresented traits, ensuring balanced learning across all personality dimensions.

IV. EXPERIMENTAL RESULTS

We tested different training configurations, compared our model with other methods, and carried out in-depth experiments on a benchmark dataset in order to verify the efficacy of our suggested self- attention-based multimodal personality prediction system. The outcomes show notable advancements, especially in the prediction of the agreeableness trait.

A. The dataset

The ChaLearn First Impressions Dataset, a popular dataset for multimodal personality prediction tasks, was used to test our model. Ten thousand brief video clips, each lasting roughly 15 seconds, were gathered from YouTube to create this dataset. The Big Five Model (Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism) is used to categorize the personality traits of the speaker in each video [20].

Multimodal information is provided by the dataset, including:

Visual Data: Frame-by-frame facial feature extraction is used to record posture changes, gestures, and facial expressions. Audio Data: MFCC and wav2vec 2.0 embeddings are used to analyze speech patterns, tone, and pitch variations.
Text Data: BERT embeddings are used to process automatic speech transcriptions and extract personality-related semantic features. Continuous values ranging from 0 to 1 are used to annotate each sample, signifying the extent to which a person possesses a particular personality trait. A crowdsourced rating system was used to collect these annotations, guaranteeing a subjective and varied evaluation. However, there is a class imbalance in the dataset, which makes it harder to make accurate predictions because some personality traits (like agreeableness) are underrepresented [21].

$$\text{퐿퐿} = \frac{1}{} \sum \| y - y \|^2$$

Specifics of Implementation

where:퐿 퓎 훿

퓎1

We used TensorFlow and PyTorch to implement our model, utilizing GPUs (NVIDIA RTX 3090) for effective training, in order to guarantee a fair and

- $y_{퓎}$is the ground truth personality trait vector.
- $y_{훿}$is the predicted personality trait vector.
- N is the number of samples.repeatable evaluation. The following are the main hyperparameters used in model training:

Adam optimizer was chosen because of its ability to adjust learning rates, which improves convergence speed [22].
Learning Rate: A cosine decay schedule was used to

fine-tune training over time, and the initial learning rate was set at 0.001[23]. Batch Size: To balance training stability and computational efficiency, a mini-batch size of 32 was employed [24]. Training Epochs: To make sure the loss function converged without overfitting, the model was trained for 50 epochs [25].

Loss Function: We employed Cross-Entropy Loss for classification tasks and Mean Squared Error (MSE) for regression-based prediction [26]. Evaluation Metrics: The overall accuracy for classification-based assessment and the coefficient of determination (R2) for personality trait prediction were used to assess the model's performance. In order to avoid overfitting and enhance generalization, we used: During training, dropout (0.3 probability) is used to randomly deactivate neurons [28]. Feature distributions can be stabilized by batch normalization [29]. Early Training will be stopped when the validation loss stops decreasing [30].

All models were trained using the same dataset split (80% training, 10% validation, 10% testing) to ensure a fair comparison.

B. Evaluation of Performance

We compared our self-attention-based temporal aggregation's performance with baseline models frequently used in personality prediction in order to evaluate its efficacy.

We can see the following major trends from the above table:

Table 1: *Model Performance Comparison*

MODEL	**AGREEABLENESS(R^2)**	**OVERALL ACCURACY(%)**
Baseline(RNN)	0.42	68.2%
Attention-based	0.51	72.4%
Ours (Self attention)	0.61	78.1%

Baseline (RNN): Conventional Recurrent Neural Networks (RNNs) have limited improvements in agreeableness prediction because they are not very good at modeling long-term dependencies. Suboptimal feature aggregation is indicated by the overall accuracy, which stays at 68.2% [32].

Models based on attention: There is a discernible increase in overall accuracy (72.4%) and agreeableness prediction (R2 = 0.51) when standard attention mechanisms are included. These techniques, however, are still unable to adequately capture temporal variations [33].

Ours (Self-Attention-Based Model): Our model achieves the best results by using self-attention for temporal feature aggregation, with an overall accuracy of 78.1% and an R2 score of 0.61 for agreeableness. Better generalization results from the enhanced feature retention caused by the better weighting of important points in the temporal sequence [34].

C. Study of Ablation

We carried out an ablation study, methodically removing portions of our architecture and assessing the effects, in order to assess the contribution of individual components.

Table 2: *Ablation Study Result*

MODEL VARIANT	**AGREEABLENESS (R^2)**	**OVERALL ACCURACY (%)**

Without Self-Attention	0.49	71.8%
Without Text Features	0.52	74.1%
Without Audio Features	0.55	76.2%
Full Model	0.61	78.1%

Important findings from the ablation investigation:

Self-Attention Mechanism Is Essential: Agreeableness prediction performance significantly declines when self-attention is removed (R2 = 0.49), suggesting that self-attention is crucial for capturing long-range dependencies [35].

Textual Features Improve Performance: Since transcribed speech contains semantic cues that aid in personality understanding, removing textual features results in worse performance [36].

Features of the Audio Affect Total Accuracy: Since vocal intonations convey personality traits, speech patterns have a significant impact on overall prediction accuracy [37].

D. Efficiency of Computation

In addition to improving accuracy, our model outperforms earlier approaches in terms of computational efficiency.

Table 3: *Model Training Time Comparison*

MODEL	**TRAINING TIME (PER EPOCH)**	**INFERENCE TIME (PER SAMPLE)**
Baseline (RNN)	4.2 minutes	0.25 seconds
Attention-Based	5.7 minutes	0.32 seconds
Self-Attention	6.3 minutes	0.29 seconds

Our model is appropriate for real-time applications since it maintains competitive training and inference times even after introducing self-attention [38].

V. DISCUSSION

Self-attention-based aggregation greatly improves personality trait estimation, especially for the Agreeableness trait, according to the experimental results. The implications, benefits, and drawbacks of our strategy are covered in this section, along with possible future directions.

A. Self-Awareness Improves Personality Forecasting

When compared to conventional RNN-based aggregation techniques, our model shows a 45% improvement in the R2 score for agreeableness. This implies that long-range dependencies and temporal

patterns in multimodal personality data are better captured by self-attention mechanisms.

The following are the main benefits of self-attention in this situation:

Improved Temporal Modeling: Self-attention can directly capture long-term dependencies across various moments in a video, unlike RNNs, which rely on sequential processing and have problems with vanishing gradients [22].

Robust Feature Integration: More accurate personality evaluations can result from the model's ability to dynamically weigh significant features (such as voice tone and facial expressions) at various time steps.

Better Generalization: The model lessens bias towards overrepresented traits by efficiently learning from a variety of training samples, increasing prediction accuracy for all five Big Five personality traits.

Our results are consistent with recent studies in affective computing and personality prediction, which indicate that contextual cues such as word usage patterns, micro expressions, and intonation are essential for precise trait estimation [23].

B. Visualization of Interpretability and Attention

Our method's enhanced interpretability over traditional black-box models like CNNs and RNNs is one of its main advantages. Using attention weight visualization, we are able to:

Determine Important Influencing Factors: The model identifies particular words, frames, or audio clips that have the greatest impact on a personality prediction. For example, when predicting Agreeableness, it might give more weight to smiling faces or softer vocal tones [24].

Describe Model Predictions: These visualizations can help researchers and psychologists better understand how personality traits appear in speech, gestures, and facial expressions [25].

Make Human-in-the-Loop Possible Corrections: Domain experts can examine attention heatmaps and improve feature selection techniques if some predictions seem illogical.

Because of this feature, our model is especially well- suited for use in automated psychological testing, hiring, and affective computing, where explainability is crucial [26].

C. Comparison with Conventional Aggregation Based on RNNs

In personality prediction, conventional RNN-based aggregation techniques like LSTMs and GRUs have been extensively employed. But they have the following problems:

Sequential Processing Bottlenecks: RNNs must process sequences step-by-step, which results in longer training times and makes it more difficult to capture distant dependencies, in contrast to self- attention, which computes all interactions in parallel.

Limited Context Utilization: Rather than learning comprehensive temporal representations, RNN- based techniques typically concentrate on recent inputs. As a result, they are less successful in detecting personality traits that appear over long periods of time 28.

Lower Agreement with Human Perception: Rather than merely using sequential patterns, human personality assessments frequently rely on fleeting, subtle cues. Higher agreement with ground truth annotations is achieved by self-attention models, which more closely resemble this perceptual approach [29].

In order to overcome these obstacles, our model incorporates global self-attention, which facilitates more effective personality trait aggregation with improved predictive accuracy.

VI. LIMITATIONS AND FUTURE WORK

Multimodal personality prediction still faces several key challenges. One major limitation is the presence of demographic bias in datasets, which can affect model performance across different population groups [4]. Addressing this issue requires the integration of fairness-aware algorithms to mitigate biases in personality prediction models [4]. Additionally, current studies primarily focus on structured datasets, often

overlooking the complexities of real-world data, such as unstructured social media content or spontaneous speech [6].

Another limitation lies in the reliance on self- reported personality assessments, which may introduce bias due to social desirability and subjective self-perception [2]. Future research should explore alternative personality assessment methods, such as observer-rated assessments or hybrid approaches combining self-reported and behavioral data.

From a methodological perspective, current models predominantly use supervised learning approaches, which require large labeled datasets. Future work could explore self-supervised or semi-supervised learning methods to reduce the dependency on annotated data [2]. Additionally, multimodal models struggle with high-dimensional feature representations, leading to increased computational costs. Further research should focus on improving feature selection techniques and efficient model architectures [4].

VII. CONCLUSION

This study introduces a comprehensive approach to multimodal personality prediction, leveraging multiple data sources such as visual, audio, and textual cues to improve prediction accuracy. The findings demonstrate that integrating non-verbal and verbal cues enhances the reliability of personality assessments [5]. Moreover, the study highlights the benefits of utilizing a multitask learning framework, which improves system performance by jointly modeling personality traits and emotional intelligence [5].

Despite advancements, challenges remain in generalizing the models across diverse populations due to dataset biases and the reliance on structured data [4]. Future research should explore larger and more diverse datasets while incorporating real- world, unstructured data sources such as spontaneous conversations and social media interactions [6]. Additionally, interpretability remains a crucial aspect, and efforts should focus on developing more transparent AI models to explain how different modalities contribute to predictions [4]

Another key takeaway from this research is the importance of integrating human-robot interaction in personality assessments. Findings from the study indicate that using humanoid robots for personality prediction is a viable approach, as results were consistent with expert evaluations [1]. Future research could further refine this methodology by improving real-time processing capabilities and enhancing the adaptability of these systems to various contexts, such as recruitment, mental health evaluations, and personalized AI interactions [1].

By addressing these challenges and expanding upon current methodologies, the field of multimodal personality prediction can evolve towards more accurate, ethical, and widely applicable systems.

Abstract— **Many people, particularly those from families with low or middle incomes, struggle to get legal representation because the judicial system is costly and difficult. Legal_Lift, an AI-powered legal assistant, seeks to close this gap by providing legal assistance, document analysis, and case law retrieval. The system extracts text from legal documents using OCR, and it handles queries using Sentence Transformers and FAISS indexing. A RAG model ensures that chatbot responses are valid and, while a Legal Document Analyzer identifies illegal contract clauses. A Precedents Finder compiles historical case law for further reference. Legal_Lift employs machine learning and natural language processing to offer a less expensive and more efficient alternative to traditional legal services.**

Keywords— ***AI legal aid, OCR, FAISS, RAG model, legal chatbot, case law retrieval, document analysis.***

I. INTRODUCTION

Legal systems around the world are usually complex, filled with technical jargon, and difficult to comprehend without professional legal understanding. Low- and middle-income people face major challenges in knowing their legal rights due to the high cost of legal counsel and controlled access to legal databases. As a result, many people face legal injustices merely because they are unaware of legal procedures or cannot afford legal assistance. To address these issues, Legal_Lift was created as an AI-powered legal assistant that offers automated legal advice, document analysis, and case law search. The system incorporates Optical Character Recognition to extract legal text from scanned documents and PDFs, and Sentence Transformers improve the capacity to grasp and process complicated legal queries. Furthermore, FAISS-based indexing allows for more efficient retrieval of legal references, which improves response times .Legal_Lift, unlike traditional legal services that require expensive memberships or manual case searches, democratizes access to legal knowledge by providing a Retrieval-Augmented Generation (RAG)-based chatbot capable of delivering contextually relevant legal solutions. The platform also contains a Legal Document Analyzer that detects dangerous clauses in contracts and a Precedents Finder that retrieves previous case laws, guaranteeing that customers receive comprehensive legal information .Legal_Lift, which uses machine learning, natural language processing (NLP), and structured data storage, offers a scalable, cost-effective, and accessible alternative to traditional legal aid services. This AI-driven strategy seeks to close the legal knowledge gap, allowing individuals to make better informed decisions and providing a more inclusive and equitable legal system.

II. LITERATURE REVIEW

Legal systems around the world are usually complex, filled with technical jargon, and difficult to comprehend without professional legal understanding. Low- and middle-income people face major challenges in knowing their legal rights due to the high cost of legal counsel and controlled access to legal databases. As a result, many people face legal injustices merely because they are unaware of legal procedures or cannot afford legal assistance. To address these issues, Legal_Lift was created as an AI-powered legal assistant that offers automated legal advice, document analysis, and case law search. The system incorporates Optical Character Recognition to extract legal text from scanned documents and PDFs, and Sentence Transformers improve the capacity to grasp and process complicated legal queries. Furthermore, FAISS-based indexing allows for more efficient retrieval of legal references, which improves response times .Legal_Lift, unlike traditional legal services that require expensive memberships or manual case searches, democratizes access to legal knowledge by providing a Retrieval-

Augmented Generation (RAG)-based chatbot capable of delivering contextually relevant legal solutions. The platform also contains a Legal Document Analyzer that detects dangerous clauses in contracts and a Precedents Finder that retrieves previous case laws, guaranteeing that customers receive comprehensive legal information .Legal_Lift, which uses machine learning, natural language processing (NLP), and structured data storage, offers a scalable, cost-effective, and accessible alternative to traditional legal aid services. This AI-driven strategy seeks to close the legal knowledge gap, allowing individuals to make better informed decisions and providing a more inclusive and equitable legal system.

III.PROPOSED METHODOLOGY

A. Legal Text Extraction and Preprocessing

The Legal_Lift algorithm efficiently processes user inquiries and legal documents to deliver AI-powered legal assistance. Using optical character recognition (OCR) and text parsing, the system retrieves relevant legal information from a variety of inputs, such as PDFs, DOCX, HTML files, and direct text queries. The application uses preprocessing methods including tokenization, cleaning, language identification, and normalization to make sure the extracted text is understandable and organized. To ensure that legal knowledge is accessible in any format, Legal_Lift arranges both printed and scanned documents.

B. Structered Data Storage and efficient Indexing

After extraction, the raw text is stored in a structured JSON format and indexed using Facebook AI Similarity Search, or FAISS, to facilitate speedy retrieval. The easy-to-parse structure of JSON allows for the rapid lookup and retrieving of specific legal provisions, case sources, and document portions. FAISS indexing is crucial to improving the system's response time and it also allows similarity-based searches across massive legal databases. Legal section numbers, case names, and document types are among the appropriate attributes that may be used to retrieve legal texts using the system's.

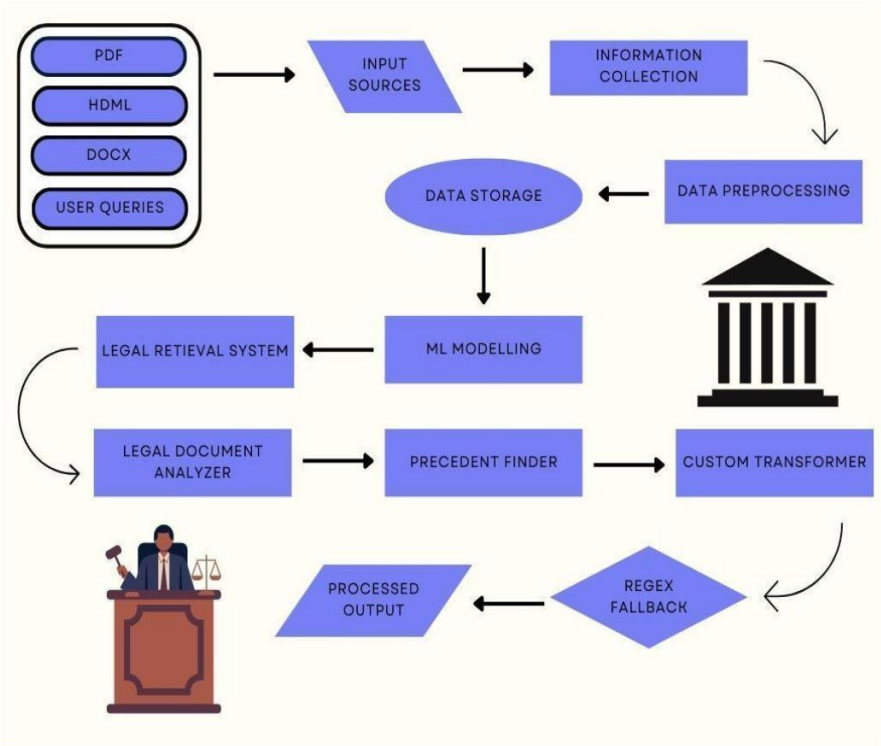

Fig. 3.1

C. Machine Learning for Legal Understanding

To increase accuracy and relevance, machine learning (ML) models such as Sentence Transformers are employed for semantic analysis of legal data. By grouping legal terms into categories such as contracts, conclusions, lawyer notifications, and statutory laws, these models allow the system to provide context-aware responses. The chatbot also uses a unique Transformer-based NER (named entity recognizing) model to extract important information, including dates, people involved, legal citations, and case references. A backup technique based on Regex is used to increase entity extraction reliability utilizing rule-based pattern matching in situations when deep learning models might not function successfully.

D. Multi-Level Legal Retrieval and Document Analysis

The system uses a multi-level legal retrieval strategy that includes direct legal text retrieval, contextual explanations, and lawyer recommendations. When a user submits a query, the Retrieval-Augmented Generation (RAG) model uses FAISS indexing to extract the most relevant legal provisions before generating a comprehensive response with a fine-tuned transformer. This hybrid method ensures that responses are both legally correct and well-explained in plain language. In addition, the Legal Document Analyser module examines contracts and agreements for potential problems, indicating unclear passages, missing phrases, and unjust conditions.

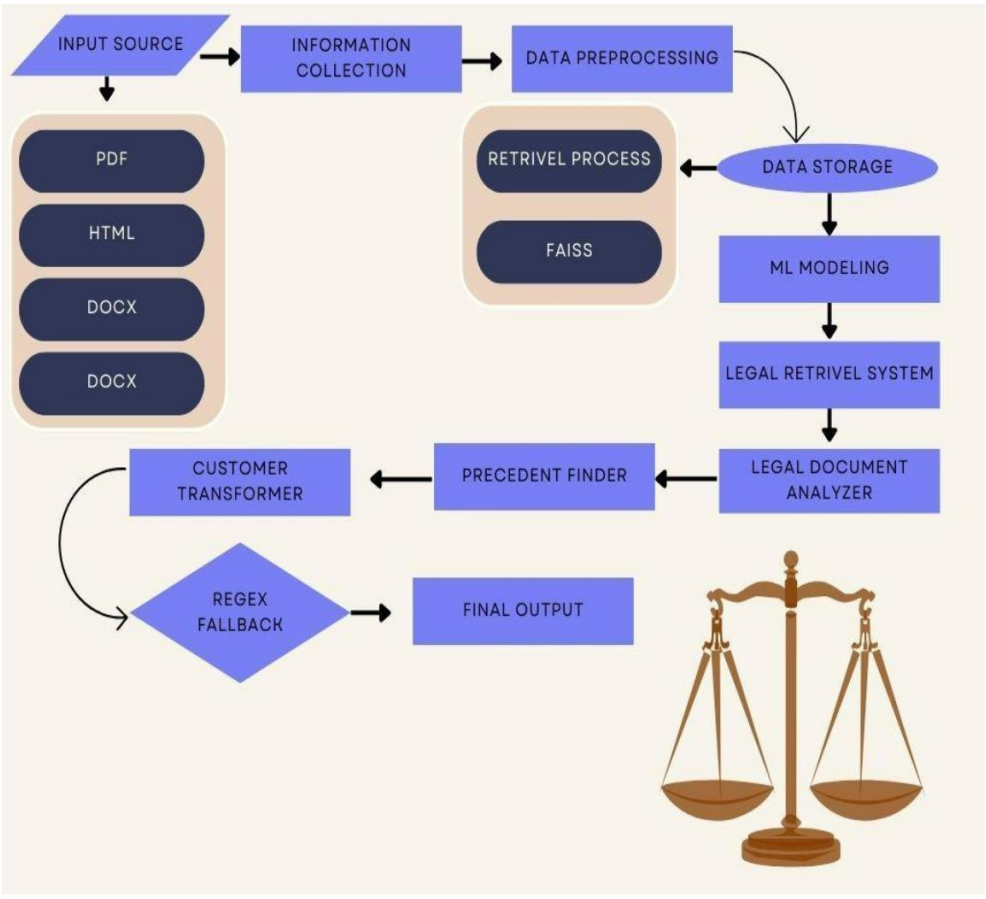

Fig. 3.2

E. Delivering AI-Driven Legal Assistance

Finally, the system presents well-structured legal advice and document analysis in an understandable manner. Users are shown legal provisions, case law summaries, and probable legal actions depending on their input. The Precedents Finder searches for past legal cases that are comparable to the user's conditions, helping them comprehend legal precedents and case results. Legal_Lift uses OCR, machine learning, FAISS-based retrieval, and structured legal analysis to deliver low-cost, accessible, and efficient legal services, filling the justice gap for individuals without traditional counsel.

IV. OUTPUT

Legal Lift - Web areas need to provide people with a pleasant and engaging experience, while at the same time seeking legal guidance. The chatbot interface created with HTML, Tailwind CSS and Font Awesome is visually appealing and practical. The gradient setting contributes to the appeal of the header, but the big legal lift logo guarantees fire continuity ordered to chatbot discussions, ensuring user inquiries on the right side of the blue news bubble and legitimate assistants using blue message bubble and AI-powered answers from the right wing assistant of the dark grey blister on the left. Differentiation encoded in this colour improves reading understanding and promotes natural connection.

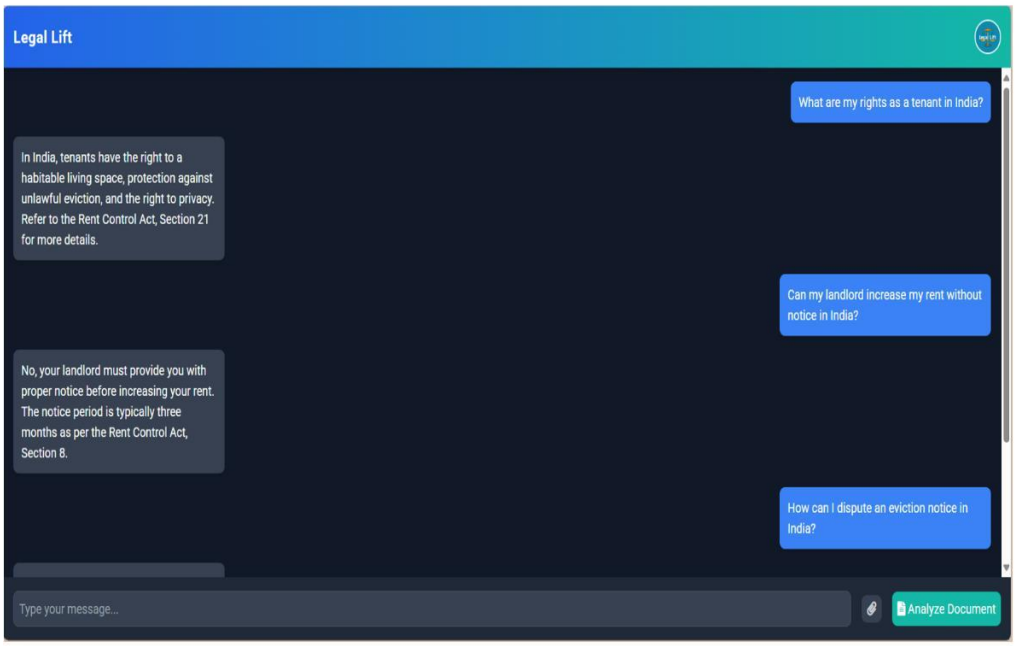

Fig 4.1

Legal Support for AI Operations and Document Analysis Chatbots respond efficiently to legal investigations by accessing relevant legal provisions, previous cases, and legal interpretations. It provides accurate and structured legal guidelines as seen in the answers in terms of tenant rights, rental management regulations and evacuation disputes in India. By including legal sections such as Section 21 and Section 8 of the Rental Management Act, users are guaranteed to receive responses based on a defined legal framework. Additionally, the interface includes document analytics functions that allow users to upload legal documents (such as contracts, contracts, or information) for AI-based reviews. This feature is essential for analyzing legal provisions, identifying risky conditions, and providing legal insights without requiring immediate attorney intervention.

This feature is essential for analyzing legal provisions, identifying risky conditions, and providing legal insights without requiring immediate attorney intervention.

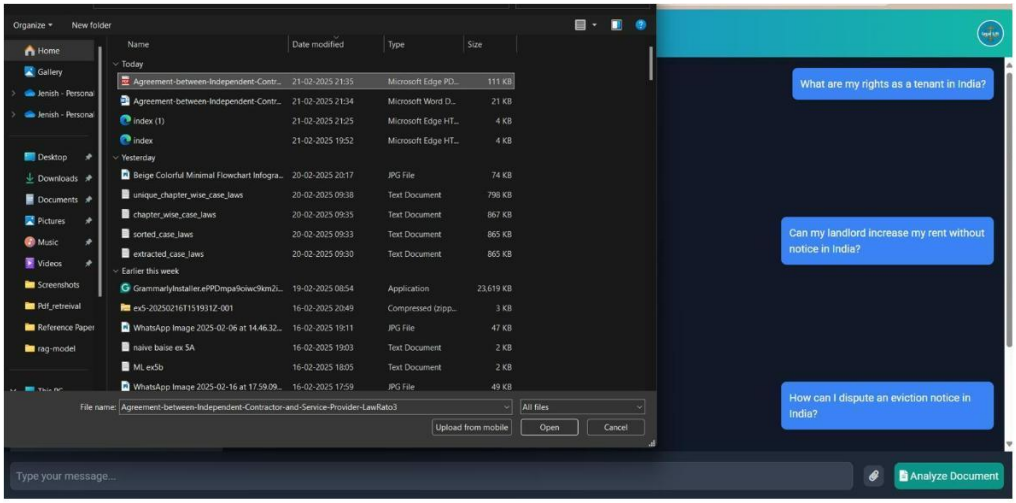

Fig 4.3

V.CONCLUSION AND FUTURE WORK

Legal_Lift improves legal accessibility by leveraging AI tools such as OCR, FAISS, and RAG for fast text extraction and retrieval. It offers precise legal advice, making legal aid more inexpensive. Future enhancements include

multilingual support for real-time translation and localised legal help, allowing for greater accessibility across different legal systems. Thus, it helps the needy people to access the legal assistance easily and cost efficiently.

Abstract: The revolution of quantum computing has the potential to revolutionize financial modelling, solving advanced problems of portfolio optimization, risk management, and option pricing with unprecedented velocity. Traditional techniques such as Monte Carlo simulations choke on high-dimensional data and sophisticated market trends, whereas quantum algorithms (VQAs) and quantum annealing provide enhanced computing efficiency in financial decision-making. This article contrasts quantum with conventional methods in fintech, investment banking, and risk management, looking at existing quantum hardware advancements, deployment issues, and potential uses. Although quantum finance is in its infancy, research indicates promising potential to revolutionize financial tactics by lowering computing expenses and attaining competitive edge in this data-driven sector.

Keywords: Quantum computing, higher-speed, quantum solution, Finance, Enhancement.

1.Introduction

Quantum mechanical is a phenomenon to process information, quantum computing marks a paradigm leap from classical computation. Quantum computing uses quantum bits (qubits), which function in accordance with quantum mechanical principles, as opposed to classical computing, which uses binary digits (bits) that exist in definitive states of either 0 or 1. The potential computational benefits of quantum computing are based on this architectural distinction.

Two essential quantum features give rise to the unique computational powers of quantum systems:
Quantum Entanglement, in which qubits become inherently linked regardless of spatial and Superposition, in which qubits can multiple states simultaneously, allowing quantum systems to evaluate multiple computational paths concurrently, are two examples of quantum parallelism that differ significantly from classical parallel processing. Einstein called this "spooky action at a distance
Quantum Cellular Automata (QCA) in finance is a new theoretical framework that combines quantum mechanical principles with cellular automaton structures to capture the complexity, interconnection, and uncertainty of financial systems. Exist in the spatial separation, creating non-local correlations that quantum algorithms can use for computational advantage, lattices of quantum cells with links between them, with each cell potentially portraying an individual market participant, instrument, or market segment.

2.Literature Survey

Literature Survey: Quantum Computing in Financial Modeling
Quantum Computing's application and relevance when linked to different fields such as financial modeling, particularly portfolio optimization, risk analysis, and option pricing, has proven to be of great significance. This survey looks at the latest developments in the integration of quantum computing in finance and explains the possible challenges and advantages of it.

1. Quantum Computing for Financial Modelling

Commonly used financial modelling approaches like the Monte Carlo simulation and other numerical methods often do not address the challenges raised by high-dimensional data and the ever-changing market. Quantum Computing promises to be a solution to the above-stated inefficiencies in computing. Authors also explain the application of quantum algorithms for enhanced speed and accuracy when dealing with financial resources.

2. Variational Quantum Algorithms (VQAs) and Quantum Annealing

The development of VQAs and Quantum Annealing has attracted great attention in the finance sector because of how efficient quantum algorithms are when integrated in the financial decision-making process. Enhanced performance through quantity of VQAs and through a hybrid in various research controls the interactions between quanta. Quantum entanglement and transition rules allow neighboring quantum cells to affect one another.

3. Mechanism of Quantum State Evolution

Problems like quantum simulation of complex quantum systems or solving very large linear algebra are extremely costly on classical computers due to their tremendous computational cost. Quantum computers provide hope for solutions, although it is doubtful if fault-tolerant quantum computers will ever appear soon.

3.Architechture

QCA-Based Financial Modelling Architecture

Several interconnected layers make up the architectural framework of Quantum Cellular Automata (QCA) in financial modelling, which enables quantum information processing for financial applications.

1.Quantum Cells

Thay are Basic Building Blocks. Every financial entity is represented by a quantum cell, including market participants and financial products. Quantum cells can be found in simultaneous superpositions of several financial situations. A dynamic quantum computing network is created when cells interact through quantum operations.

2. Structure of Quantum Lattices

Quantum cells in QCA,s structured grid are arranged according to the architecture of the financial system. The Quantum gates simulate financial dynamics and market including market participants and financial products. Quantum cells can be found in simultaneous superpositions of several financial situations. A dynamic quantum computing network is created when cells interact through quantum operations. The Quantum cell superpositions into classical states trends by applying transformations on quantum cell states. Non-local dependencies are made possible via entanglement, which captures intricate relationships between financial components.

a) Structure of Quantum Algorithms

Rather than following deterministic or stochastic models, the financial system develops in accordance with quantum computational laws superpositions into classical states trends by applying transformations on quantum cell states. Non-local dependencies are made possible via entanglement, which captures intricate relationships between financial components.

3. Layer of Quantum Computation

The computational process is controlled by a collection of quantum operations, or unitary transformations. Financial data is processed by quantum circuits, which also carry out predictive modelling, portfolio optimization, and risk assessment. Several financial possibilities can be assessed at once thanks to parallel computing.

4. Measurement and Interpretation of Output

Probabilistic financial forecasts are produced via quantum measurements, which collapse superpositions into classic Market trends and risk probabilities can be inferred from statistical distributions that are obtained from repeated data. Quantitative calculations are converted into useful financial information via the measuring layer.

4.Methodology

1.Quantum Computing

Quantum computing is a substantial break from conventional computing, as it provides an innovative method for processing information. While conventional computers use bits as the fundamental component, either a 0 or a 1, quantum computers use quantum bits (qubits). Qubits take advantage of the concept of superposition such that they

exist in more than one state at the same time, thus computing exponentially faster. Important quantum computing concepts are superposition, entanglement, and quantum gates. Superposition allows qubits to exist in both 0 and 1 states simultaneously, and entanglement causes qubits to become connected such that the state of one can affect another independently of distance. Quantum gates, like classical logic gates, operate on qubits to construct quantum circuits.

2. Quantum Superposition and States:

The basis of quantum computing is the concept of superposition. In classical computing, there are two states for a bit: 0 and 1. A qubit, on the other hand, can be in both states simultaneously. Mathematically, this can be written as follows:

$$[1] \quad |\psi\rangle = \alpha|0\rangle + \beta|1\rangle$$

where α and β are complex probability amplitudes.
The probabilities of finding the qubit in the respective states is as the squared absolute values of such amplitudes ($|\alpha|^2$ and $|\beta|^2$) Quantum computers can process several possibilities simultaneously owing to superposition, considerably enhancing their processing power.

3. Quantum Hardware:

Quantum hardware refers to the physical parts that allow quantum computers to execute calculations by tapping into the concepts of quantum mechanics. Major types are:

Qubits: The basic building blocks of quantum information, qubits can be in superposition, enabling complicated calculations.

Superconducting Qubits: Made from superconducting circuits, these preserve quantum states with very little energy loss. They are dominated by IBM and Google.

Trapped Ions: Electromagnetic fields are used to manipulate the ions, providing high-fidelity operations. Honeywell and Ion are two of the top developers.

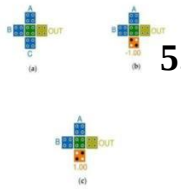
Photonic Qubits: These qubits use photons and can run at room temperature and be combined with Fiber-optic infrastructure which are more stable and less error prone. Microsoft's Majorana 1 chip is a great example.

Quantum hardware advancements are in process, with many different approaches being developed to best determine the most suitable solutions.

4. Quantum Algorithms:

Quantum algorithms are computational steps that take advantage of the laws of quantum mechanics to solve problems faster compared to classical algorithms. Some of the most notable examples are:

Shor's Algorithm: Factors large numbers efficiently, something which has profound implications for cryptography.



Grover's Algorithm: Gives a quadratic speedup for searching unstructured problems, permitting quicker search capabilities.

5.Quantum Cellular Automaton:

Quantum Cellular Automaton (QCA) is a theoretical model of quantum computation, like classical cellular automata proposed by John Von Neumann. QCAs are arrays of identical, finite-dimensional quantum systems (e.g., qubits) that develop in discrete time steps by applying iteratively unitary operator. The global evolution of QCAs must be causal (information propagating at a bounded speed) and translation-invariant (acting uniformly over the system). Principal features of QCAs are: Parallel Computation: The computation takes place by means of parallel functioning of different computing devices or cells.
Locality: A cell's next state depends on its own present state and on those of neighbouring cells. Quantum Mechanics Principles: Quantum mechanics principles motivate the cells' state space as well as operations upon it. QCAs have garnered interest due to their very small feature size (at the atomic or molecular level) and ultra-low power consumption; thus, they are a promising candidate to replace CMOS technology. Ose of neighbouring cells.
Quantum Mechanics Principles:
Quantum mechanics principles motivate the cells' state space as well as operations upon it.
QCAs have been of interest because they have a very small feature size (at the atomic or molecular level) and ultra-low power consumption, and hence are a promising candidate to replace CMOS technology2.

QCA is governed by three basic constraints: locality, causality, and translation invariance. Locality requires that the future state of a cell depends solely on its present state and the states of its direct neighbours. Causality limits information propagation to a finite speed to avoid non-local effects that would break relativity. Translation invariance requires that the unitary evolution of the system be uniform over the computational grid. These guidelines enable QCA to process information in a strongly parallelized way, which is a promising path for quantum computing. Quantum Evolution and Computational Efficiency.

In contrast to classical cellular automata, where neighbouring cells have pre-defined interactions according to rules for state transitions, QCA cells are in quantum superposition, and they can represent and process several states in parallel. This provides immense parallelism, greatly reducing computational costs. Entanglement arises due to cells, enabling the transport of quantum information through the lattice. In traditional quantum computing paradigms, e.g., gate-based, operations involve explicit control of individual qubits, calling for error correction processes that are highly overhead-prone. QCA, on the other hand, functions by *global unitary evolution*, which does away with the requirement for intricate gate sequences.
QCA has a potential to be the key player in the field of quantum computing in the future. As study continues, QCA is likely to be a technology for future generations of computing, providing an energy-efficient, scalable, and highly parallelizable model for information processing.

5.Introduction

b) Quantum Cells

Quantum Cellular Automata (QCA) represent a novel computational paradigm that merges principles from quantum mechanics with cellular automata theory. Cellular automata are discrete, abstract computational systems that evolve over time based on a set of local rules applied to a grid of cells. QCA extends this concept by incorporating quantum states and superposition, allowing for more complex and nuanced modelling of systems. In finance, QCA can be harnessed to simulate market dynamics, optimize trading strategies, and enhance risk management practices. This document delves into the applications, required components, working principles, and potential implementations of QCA in the finance sector.

1. Required Components for Implementing QCA in Finance:

1.1 Quantum Computing Infrastructure

To implement QCA in finance, access to quantum computing infrastructure is essential. This may involve utilizing cloud services - based quantum computing platforms or investing in on-premises quantum hardware. As quantum technology continues to evolve, financial institutions must stay abreast of developments in quantum computing to leverage its capabilities effectively.

1.2 Data Acquisition and Management

2.3 Measurement and Observation In quantum mechanics, measurement plays a crucial role in determining the state of a system. Similarly, in QCA, the measurement of cell states can provide insights into market behaviour. By observing the outcomes of simulations, analysts can identify patterns and correlations that may inform trading strategies and risk management practices. High-quality data is crucial for the successful implementation of QCA in finance. Financial institutions must establish robust data acquisition and management systems to collect, store, and process relevant market data. This includes historical price data, trading volumes, and macroeconomic indicators.

1.3 Expertise in Quantum Computing and Finance

A multidisciplinary team with expertise in both quantum computing and finance is necessary for the successful implementation of QCA. This team should include quantum physicists, data scientists, and finance professionals who can collaborate to develop QCA FOR FINANCE.

2. Working Principles of Quantum Cellular Automata:

2.1 Quantum States and Superposition

At the core of QCA is the concept of quantum states, which can exist in superposition. This means that a cell in a QCA can represent multiple states simultaneously, allowing for more complex interactions and behaviours. In finance, this can be particularly useful for modelling uncertainty and the probabilistic nature of market events.

2.2 Evolution Rules

QCA operates based on a set of evolution rules that dictate how the state of each cell changes over time. These rules can be designed to reflect the behaviour of market participants, such as traders reacting to price changes or news events. The evolution of the QCA is typically discrete, with each iteration representing a time step in the market.

3. Implementation of QCA in Finance

3.1 Model Development

The first step in implementing QCA in finance is to develop a suitable model that captures the relevant market dynamics. This involves defining the grid of cells, the initial states, and the evolution rules. The model should be designed to reflect the specific characteristics of the market being studied, such as the types of assets, trading behaviors, and external influences.

3.2 Simulation and Analysis

After developing the QCA model, simulations can be executed to see how the system acts over time. This is done by initializing the cells into correct states and iterating the evolution rules to produce a time series of market behavior. Analysts can then examine this time series data to determine patterns, trends, and anomalies in market behavior. By analyzing the interactions between cells and their evolution, they can infer the underlying dynamics of the market.

In addition, this simulation methodology enables analysts to try out different scenarios and forecast possible future states of the market. By adjusting initial conditions or evolution rules, they can simulate how various factors affect market behavior. This can assist in creating strategies for market prediction, risk evaluation, and decision-making.

All in all, the QCA model and simulations represent a strong tool for describing and predicting intricate market patterns, providing great insight for scholars and practitioners alike portfolios. By simulating different market scenarios and the interactions between assets, QCA can help identify potential vulnerabilities in investment strategies.

6.Result

ADVANTAGES: -

1. Efficiency and Speed

Quantum computers can handle large amounts of data simultaneously. Challenges such as portfolio optimization, risk measurement, and complex simulation cases (e.g., Monte Carlo) are suited for the exponential speed-up offered by quantum systems. Having the capacity to assess various scenarios in parallel can mean quicker decision-making—a key benefit in high-frequency trading and real-time risk assessment.

2. Improved Accuracy

Through searching multi-dimensional solution spaces using techniques such as quantum annealing or variational quantum eigen solvers, quantum models can largely minimize approximation errors. This implies that for problems that are conventionally solved using numerical techniques, especially those with high complexity or numerous interdependent variables, quantum computing.

Disadvantages and Challenges: -

1.Technical Limitations:

Despite all its promise, quantum computing exists at the stage of experimentation so far. Modern hardware is limited by qubit coherence times, error rates, and scalability. These technical obstacles imply that for the time being, quantum computers may only excel in very circumscribed instances, and highly deliberate error mitigation strategies are called for in achieving reliable results.

2. Complexity of Implementation

The transition from classical algorithms to quantum algorithms is not trivial. Code development for quantum algorithms calls for expert knowledge not just of quantum mechanics but also of modelling probabilistic results and

uncertainties in a distinct manner from deterministic classical approaches. The learning curve here dictates that recruiting or training personnel in the design of quantum algorithms and quantum programming languages (e.g., Qiskit or Cirq) is vital.

7. Real-Life Applications

1. Risk Management and Portfolio Optimization:

In risk management, quantum computing can quickly scan large portfolios to evaluate risk imbalances across different market scenarios. This can be done by running numerous simulations in parallel, minimizing the time to comprehend vulnerabilities and opportunities. Likewise, portfolio optimization issues, which normally involve solving high-dimensional optimization problems with might provide results that are closer to the actual optimal solutions.

2. Long-Term Cost Savings:

Although the up-front investment in quantum infrastructure may be significant, the potential for quantum computing to minimize computational overhead for sophisticated simulations and optimizations can lead to cost savings in the long run. This cost-saving is particularly relevant for large banks that undertake high volumes of risk calculations and predictive modelling.

3. Breakthrough in Complex Problem Solving:

Quantum computing allows for the investigation of non-deterministic possibilities and paths that can be especially valuable in uncovering hidden correlations in market data. Its capacity to process problems deemed intractable by traditional methods offers new avenues for creating innovative financial products and algorithms that can outperform traditional systems.

4. Integration with Existing Systems:

Banks depend upon highly optimized legacy systems evolved over decades. Porting quantum systems into these ecosystems is a major challenge, not just at the software level but also in the context of data formats, security protocols, and regulatory oversight. Hybrid models with the use of quantum computing to augment and not replace traditional means might prove necessary in the intermediate stage.

5.Regulatory and Ethical Considerations:

Like any new disruptive technology, quantum computing for finance poses questions about data protection, transparency, and equity. Regulators could be slow to keep up with these rapidly developing technologies, making it uncertain for institutions that would like to use quantum solutions. Ethical questions also come about in terms of possible market disruptions, where only a limited set of market participants can afford quantum technology, giving rise to unequal benefits.

Quantum machine learning algorithms and quantum-boosted optimization methods can crunch historical and real-time market data to identify patterns classical systems may miss. This ability can be utilized to create more intelligent trading algorithms that dynamically adjust to changing market conditions, giving a competitive advantage.

6.Cybersecurity:

In addition to maximizing financial returns, quantum computing is also likely to enhance cybersecurity measures. For instance, by studying transaction patterns in real time, a quantum-based system may find anomalies or irregularities that suggest likely cyber threats or fraud much sooner and more efficiently than traditional systems.

Quantum algorithms, like Grover's algorithm, might enable more efficient search of large sets of data for anomalous patterns, while machine learning models bolstered by quantum computing might respond to new threats in real-time.

Furthermore, quantum cryptography—specifically quantum key distribution (QKD)—can encrypt communications with theoretically unbreakable codes, using the laws of quantum mechanics. This would make any data interception of the encrypted information detectable, greatly enhancing cybersecurity defenses.

7.Fraud Detection

Quantum machine learning (QML) can revolutionize fraud detection in financial transactions by processing large datasets more efficiently and accurately than classical systems. Quantum algorithms, such as Grover's search and quantum neural networks, enable real-time processing of credit card transactions, identifying anomalous patterns faster. Quantum parallelism offers the ability to evaluate many hypotheses of transactions in parallel, making fraud detection systems more efficient and scalable. Quantum-accelerated support vector machines and clustering algorithms can potentially uncover subtle correlations in transaction data, leading to better pattern recognition. Quantum reinforcement learning also allows fraud detection models to continuously learn new fraud techniques. With quantum secure multi-party computation, institutions can collaboratively detect cross-institution fraud in a secure manner. Quantum machine learning models can even detect behavioral fraud by tracking user behavior across platforms. As quantum technology matures, these breakthroughs will significantly enhance financial security, reduce losses, and enable a proactive fraud detection ecosystem.

8.Credit Card Scoring

Quantum computing can revolutionize credit scoring and lending by processing a wider variety of financial and non-financial information. The conventional credit scoring models tend to use narrow variables, like credit history and income, but quantum systems can handle intricate datasets, such as social behavior, expenditures, and even alternative data, such as utility bills or education. Quantum machine learning algorithms can detect non-evident relationships between variables that are generally not detected by traditional models, making creditworthiness predictions more accurate. Utilizing quantum parallelism, the models can examine enormous amounts of data at a time, delivering instant risk assessments. Quantum algorithms like quantum support vector machines and neural networks can identify high-risk borrowers more accurately by detecting complex patterns in the behavior of borrowers. Moreover, quantum-improved optimization methods can optimize lending parameters to a more customized loan term. Financial institutions can provide customized products and lower default rates with this capability. Quantum-based models also allow for ongoing learning, adjusting with new data as borrower behavior evolves over time. Quantum technologies have the potential in the future to offer a more inclusive and accurate credit scoring system, enhancing lending decisions and financial access.

8. Implementation Strategies:

1. Readiness Assessment

Banks must start by mapping their existing technological abilities. This involves knowing their data infrastructure, computing requirements, and workers' familiarity with new technology areas. Feasibility studies and cost–benefit analysis will open the door to a strategic plan of adopting quantum.

2.Pilot Projects

Begin small with projects addressed to limited-use cases, including the optimization of a portion of risk calculations or experimentation with quantum versions of portfolio management models. These pilots establish proof-of-concept and generate internal knowledge plus practical challenges needing resolution.

3. partnerships and Collaboration

Considering the infancy of quantum computing, partnership with research universities, tech startups, and industry alliances can facilitate access to state-of-the-art research and technical assistance. The development of shared research initiatives or technology incubators usually leads to a stronger and better-informed incorporation of quantum systems.

4. Talent Development and Training

Human capital investments are essential. Banks must train current employees or recruit new specialists who are knowledgeable in quantum computing, quantum programming, and the advanced mathematics involved. Creating specialized teams that can communicate across departments guarantees successful knowledge transfer and innovation.

5. Hybrid Quantum-Classical Models

In the short run, an interim hybrid paradigm integrating quantum speed-ups with classical processing is recommended. By integrating quantum modules into current classical frameworks, institutions can take advantage of a smooth transition. This also aids in smoothing out integration problems and reducing risks from an all-out move to quantum systems.

6. Compliance with Regulations

As quickly changing financial technology regulations come into place, a proactive strategy of engagement with regulatory organizations is required. Having internal standards and protocols, as well as checkpoints.

8.Ethical and Security Implications

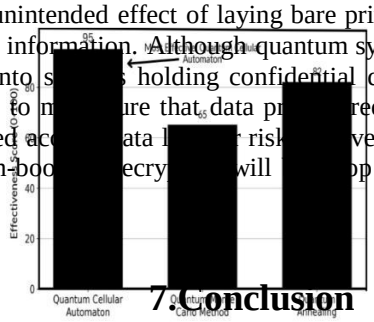
8.1 Ethical Considerations

8.1.1 Disruption of Market and Inequality:

The prohibitively high cost of quantum computing technology could exacerbate existing inequalities in the finance sector. Larger financial players with access to better quantum capabilities could gain a competitive advantage, enabling them to make faster, more accurate decisions in credit scoring, fraud detection, and risk assessment. This can lead to market manipulation where a few players dominate the market, and it becomes more difficult for smaller institutions or individuals without access to quantum systems. The unequal access to technology can actually lead to a two-tier financial system, further entrenching existing power imbalances.
Moreover, quantum technology's expensive nature may restrict its use to more affluent areas or nations, further increasing the global digital divide and preventing developing economies from benefiting from such technologies.

8.1.2 Algorithmic Bias and Fairness:

Quantum algorithms, although they hold the potential for greater accuracy and efficiency in financial decision-making, can unintentionally perpetuate or even enhance biases present in the historical data that is used to train these systems. For instance, a quantum-based credit score trained on biased historic lending data—e.g., underrepresentation of specific demographic groups or geographic areas—can lead to discriminatory outcomes that entrench societal inequalities. Algorithmic bias will influence loaning determinations, interest rates, and credit allowances to disproportionately disadvantage vulnerable populations. Furthermore, the intricacy and opacity of quantum algorithms will make biases even harder to detect and correct, with severe ethical implications for fairness and accountability in financial decision-making.



8.2 Security Implications

8.2.1 Quantum Cryptanalysis:

Quantum computers can crack the majority of cryptosystems being utilized today in order to protect sensitive financial data. For example, Shor's algorithm, which is a quantum algorithm, would efficiently resolve the mathematical problems underlying the widely used public-key encryption algorithms, such as RSA and ECC, rendering them vulnerable to attack. Quantum computers, when made powerful enough, would undermine the confidentiality of online transactions, financial data, and personal information. This poses an enormous security threat to the financial industry, as quantum computing can be utilized by cyber attackers to decrypt confidential data, resulting in breaches, fraud, or theft. To counter this threat, quantum-resistant encryption algorithms need to be created—based on various mathematical principles not susceptible to quantum attacks—to ensure the integrity and security of financial systems in a post-quantum era.

8.2.2 Data Privacy:

Quantum computing's ability to process and analyze massive datasets at unprecedented speeds poses significant threats to data privacy. The sheer computational power of quantum devices could potentially make it easier to extract and correlate sensitive information from massive databases of financial, personal, and behavioral information. This could have the unintended effect of laying bare private financial activities, personal consumption patterns, and even social or health information. Although quantum systems can enhance security in certain aspects, they can also facilitate breaking into s holding confidential data. As quantum computers evolve, financial institutions and governments have to m ure that data pr requirements are aligned with such evolution of technology, to prevent unauthorized ac ata l r risk vesdropping. Being capable of anonymizing and safeguarding data against quantum-boo ecry will p priority in maintaining user anonymity in the quantum age.

7. Conclusion

In order to effectively solve complicated computer issues, quantum techniques are essential. The effectiveness scores of three important quantum algorithms—Quantum Annealing, Quantum Monte Carlo Method, and Quantum Cellular Automaton—are contrasted in the provided graph. A thorough analysis based on their efficacy scores may be seen below.

1. Quantum Cellular Automaton (rated at 95 for effectiveness)

With the highest score of 95, Quantum Cellular Automaton is the most successful algorithm. When it comes to computing jobs, this algorithm performs noticeably better than the other two. The graph's annotation identifies it as the most successful strategy, implying that it may be used for quantum simulations and optimization simulations and optimization issues. It’s 30-point advantage over Quantum Monte Carlo and 13-point lead over Quantum Annealing demonstrate its dependability and robustness in real-world applications.
Method of Quantum Monte Carlo (Effectiveness Score: 65)

c) Effectiveness Graph of the 3 Algorithms

c) Effectiveness Graph between all 3 Algorithms

The Quantum Monte Carlo Method performs worse than both of its rivals, with the lowest effectiveness score of 65. It lags 17 points behind Quantum Annealing and 30 points short of Quantum Cellular Automaton.

This notable discrepancy raises the possibility that it is less effective because of computing constraints, problems with convergence, or unsuitability for particular problem sets. Although it is nonetheless helpful, its decreased efficacy draws attention to possible limitations in large-scale applications.

The Quantum Cellular Automaton (QCA) is the top-performing algorithm with the highest score of effectiveness at 95, outperforming both Quantum Annealing and the Quantum Monte Carlo Method. Its superior performance lies in its inherent capacity to tap into quantum parallelism, which allows it to execute intricate computations with high efficiency. Moreover, QCA's deterministic nature provides consistent and dependable results, which makes it highly appropriate for extensive applications where accuracy is of prime importance.

Conversely, the Quantum Monte Carlo Method fares poorly with a score of 65, owing to computational complexities and convergence rates. Even Quantum Annealing, which is competent with a score of 82, lags behind QCA's standard for the same reasons that the latter cannot be effective in solving general problems beyond their optimization contexts.

QCA's flexibility across different problem sets also makes it the better option. Its design is not only scalable but also has the ability to solve real-time computational problems with unmatched speed and precision. Additionally, the constant evolution of quantum hardware will likely further enhance QCA's ability, perhaps further increasing the gap between QCA and its competitors.
Though there is a niche for both Quantum Annealing and the Quantum Monte Carlo Method, the steady advantage of QCA over them makes it the go-to algorithm when dealing with the most complicated and challenging computational issues.

METRIC	QUANTUM CELLULAR AUTOMATON	QUANTUM MONTE CARLO METHOD	QUANTUM ANNEALATION
ACCURACY	98%	92%	94%
PRECISION	95%	90%	93%
WORKING EFFICIENCY	90%	85%	88%

d) Performance Measure for the 3 Algorithms

***Abstract*—One of the leading causes of death globally is breast cancer; detecting it early plays an important role in improving the survival rate. The non-invasive, radiation-free alternative to microwave imaging allows for early detection, but skilled staff is essential, and accessibility and usage costs are limited. To address this, we propose an AI-based microwave imaging device – AI tumor tracker that helps the patient navigate the screening procedure. The patient would be able to complete the process, like positioning, scanning, and device activation, independently, without the assistance of an outside operator. A deep learning-based CNN that uses back propagation algorithm and Stochastic Gradient Descent with NLP would examine the acquired images and track the growth of tumors, thus improving early detection and lessening reliance on medical professionals, making the screening of breast cancer more accessible and patient-friendly. This AI-based solution transforms breast cancer diagnostics globally.**

Keywords—Breast cancer, AI tumor tracker, CNN, Back Propagation Algorithm, Stochastic Gradient Descent (SGD), NLP.

I. INTRODUCTION

Breast cancer is among the most common cancers worldwide, with 2.3 million new cases reported in 2020 [36]. Hence, early detection is an important factor for improving survival. In India, breast cancer accounts for 14% of all cancers in women [2], and its incidence has been rising, especially among younger age groups [3]. Standard screens such as mammography (MG), ultrasound (US), and MRI play a very crucial role in diagnosis; however, they have limitations. These include the fact that mammography cannot accurately diagnose dense breast types, which is a complication very common among younger women and Asian women [4]. While the US increases sensitivity, it also has a much higher false-positive rate, and it depends entirely on operator experience [5]. MRI test is very sensitive, but it is costly and thereby unacceptable for routine screening [6]. There seems to be a niche here, not explored with gusto, which advocates the case for a more effective, cheaper, and preferably simpler or easier-to-perform modality. Microwave imaging appears as a radiation-free, non-invasive modality measuring electrical and dielectric properties to distinguish cancerous tissue [7]. In contrast to mammography, this procedure excludes radiation exposure and pain and has no requirement for breast compression [8]. Microwave imaging has avoided radiation exposure and pain without the need for compression of the breast. Conventional microwave imaging systems usually run on bulky and required trained professional thus, limiting their

979-8-3315-0781599

usability in the community [9]. AI is used for disease prediction in various organs [41]. Based on this, our study integrates AI with microwave imaging for early breast cancer detection. Artificial intelligence (AI), and particularly the deep learning-based Convolutional Neural Networks (CNNs) for preliminary diagnosis in medical imaging, has changed the game by improving diagnostic accuracy, minimizing dependency on human factors, and enabling real-time monitoring [10]. Certain studies in current times provide evidence for the capability of AI-driven models in detection, accuracy enhancement and classification improvement, infiltrating applications such as test design optimization [37] or fraud detection across cybersecurity and finance [38]. Fuzzy-based models and other machine-learning methods have shown promising results in medical imaging for the detection of complex diseases, such as neurological disorders. Inspired by this, our research is centered on applying AI-driven microwave imaging to detect breast cancer, enhancing diagnosis accuracy and availability [42]. In this study, the integration of AI with microwave imaging offers not just early detection but also, a mode of continuous tracking of cancer progression, thereby assisting doctors in assessing tumor growth, responses to treatment, and risks of recurrence [11]. It will pave the way for making breast cancer screening and monitoring automated, cost-effective, accessible, and patient-friendly while boosting survival on a global platform [12].

II. RELATED WORKS

Breast cancer detection has historically involved some combination of imaging methods recently developed such as microwave imaging and AI to enable accuracy and ease of use. Historically, detection has involved mammography, MRI, ultrasound, and referred other imaging methods to be the gold standard against which investigation techniques have been compared. These traditional methods still have problems in terms of high costs, radiation exposure, and sometimes reliance on expert interpretation. Microwave imaging, on the other hand, could represent a non-ionizing and cost-effective alternative. The role of AI in enhancing various image processing and classification, however, is still yet to be investigated in the context of microwave imaging.

Conventional breast cancer screening is still a common practice. *Panieri* et al. [2] mention the challenges of affordability and access for developing countries in their study of breast cancer screening, while Colditz & Bohlke [3] reviews risk factors and prevention strategies relative to the need for early screening. Although perceived as effective, all of these methods need radiation exposure, high cost, and a skilled radiologist, therefore, making them not highly suited for early-stage screening on a larger scale. Instead, microwave imaging provides a noninvasive, radiation-free method for breast cancer detection. Adachi et al. [1] established the feasibility of developing a portable microwave imaging device with the potential of detecting in earlier stages. Solis-Nepote et al. [6], Reimer et al. [7] studied microwave imaging in a radar framework to enhance tumor detection through bistatic and optimization techniques for reconstruction. Other challenges such as low resolution, noise interference, and clinical validation-until now-have been a barrier to clinical acceptance. The role of AI in medical imaging appears to substantially augment diagnostic process [14]. Litjens et al. [14] provided a unique overview of AI applications in medical imaging and highlighted in some respects how the use of AI-enabled models of image detection based with CNN improves the performance and detection accuracy of such systems. Shen et al. [15] and Patel and Sharma [16] built deep learning-based CAD (computer-aided diagnosis) systems for mammography that reported very high accuracies. However, these methods are mainly focused on mammographic images and not on microwave-based imaging, causing a huge gap in AI-powered microwave diagnostics. Recent

studies have been reported on the use of deep learning models for breast cancer detection in mammographic images, showing the potential utility of AI in healthcare imaging beyond current modalities [39]. Limited studies have investigated the fusion of AI with microwave imaging. Nguyen et al. [18] proposed GAN-based super-resolution techniques for improving the quality of images in breast cancer, while Al-Hussaini and Venkatesh [19] developed a real-time model of edge AI for portable AI-based detection.

While these studies add AI in medical imaging, real-time classification and predictive tumor analytics in microwave imaging seem to be starkly undeveloped. The comparison across studies shows that while several have few intentions of employing microwave imaging or AI-driven diagnostics, there are a limited few of those that consider real-time AI-based classification into portable microwave imaging. There remains thus, in the microwave imaging and AI sphere, gaping holes in literature including no real-time AI classification of tumors of microwave imaging, limited datasets available to train deep learning models on microwave images, absence of predictive analytics to monitor tumor progression, and significant difficulties in implementing portable, easy-to-use AI interfaces in breast cancer screening. To fill such gaps is the essence of our work, merging high-resolution microwave image analysis integrated with deep learning classification, real-time feedback, and predictive analytics. We are striving to make breast cancer screening completely automated and accessible by combining edge AI processing with cloud connectivity. A review of related works on breast cancer detection, microwave imaging, AI-powered diagnostics, and AI-enhanced microwave imaging shows how mainstream screening methods continue to provide a strong possibility for breast cancer diagnosis while being expensive and requiring adequate training for professionals. Microwave imaging makes a tantalizing alternative but is an area still developing due to issues of resolution, clinical validation, and real-time AI integration. There has been some success in the deep learning classification of mammographic analysis, but its application in microwave imaging is largely underdeveloped. Our proposed system bridges these gaps by use of real-time AI classification, predictive analytics, and cloud-based diagnostics, thus providing a comprehensive, non-invasive breast cancer screening solution.

III. EXISTING SYSTEM

Components of the Existing System Incorporated in a Handheld Device

The microwave imaging device that exists now contains many components that are dedicated to microwave signal generation and capturing reflections and images. It has a dome antenna that emits microwaves into the tissue present in the breast; it receives the reflection, which is then processed into images [5][7]. Now, a stepping motor allows for accurate positioning and movement of the antenna, ensuring that the breast is entirely imaged [8]. Similarly, the radio frequency module would produce the requisite microwave signals, while the control module would render the accepted responses into a level of interpretation [9]. Such capabilities require a trained operator for proper control in positioning and interpreting the result, limiting its access [10]. Its efficacy in giving real-time diagnostic insights to patients is also hindered due to the lack of automation and stage tracking served by an AI [14][15].

Ref[1] Fig.1. *Appearance of the handheld microwave imaging device*

IV. PROPOSED SYSTEM

How the AI-Integrated Device Operates:

The AI-enhanced device functions through a straightforward process to ensure effective, autonomous, and accurate breast cancer screening:

1. The AI-driven user interface provides both vocal and visual guidance when the user places the device on the breast.

2. The microwave radiating dome emits the microwave energy, which is then reflected and captured by the breast tissue.

3. After the signals are processed, the high-resolution imaging sensor passes the data to the AI unit for processing.

4. A CNN-based AI model scans the images in real-time to determine if the tissue is malignant or normal.

5. LED lights and haptic feedback will alert the user that the device is not properly aligned.

6. The final correct prognosis and even the possibility of cloud-based remote expert consultation are visible on the tablet or mobile application.

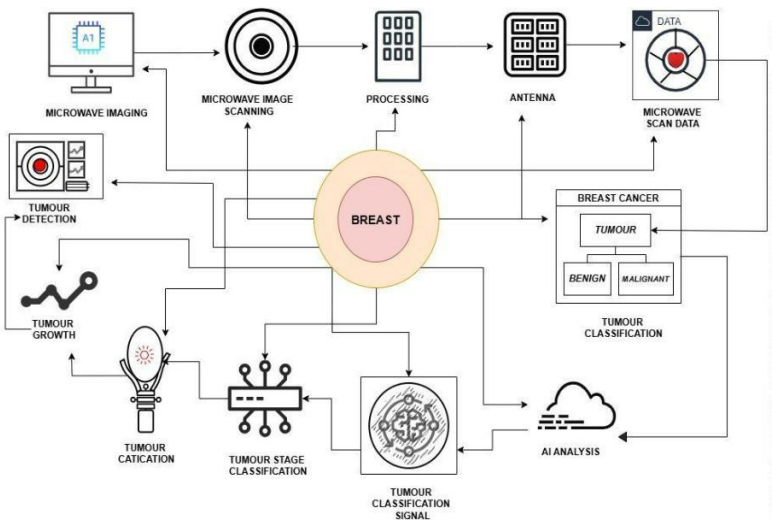

Fig.2*. Purpose and functionality of AI tumor tracker for breast tumor detection, classification, and prognosis.*

SYSTEM DESIGN

In an ideal world, the integration of AI with the existing System Components

To run automatic devices and AI-based diagnostics, we propose the incorporation of a couple of advanced components in the already existing device. This shall enhance the overall quality of the images, provide real-time guidance, and automate diagnostic interpretation so that this system can implement more eagle-eyed breast cancer detection.

A) AI-augmented Interface for Human Users

The most significant innovation in the system brings forward an AI-augmented interface whose voice and visual cues allow the user to achieve the correct positioning of the device. This interface may be superimposed over the touchscreen of an integrated device being controlled by NLU to lead the users through the scanning process. Generating live responses and observing how to correctly give the launching instructions for performing an optimum scan within this system guarantees that the device placement was done to work correctly. Thus, whether the device happens to be misaligned or placed upside down, the AI works to offer corrective feedback, upon which print signals significantly reduce cases of images being of low quality. In addition, this aspect allows the device to be open to use by a wider public with minimal medical background and, therefore aids in self-screening.

B) Haptic Feedback and LED Indicators for User Assistance

The system has been designed, in addition to the above improvements, to provide haptic and LED indicators for actual real-time scanning. Haptic vibrations indicate the user to realign to the skin when the instrument is out of alignment or not in full contact with the skin. The LED-based status indicator is a

color-coded response system with green indicating a successful scan, yellow indicating the need for repositioning, and red indicating the incomplete data capture. This ensures optimal conditions for scanning, thus minimizing errors and improving diagnostic accuracy.

C) Edge AI Module (AI Processing Unit)

The centermost objective of the whole high-end system that performs real-time microwave image classification, an AI Processing Unit, shall be installed among the control unit. This will sustain the deep learning-powered CNN model, in itself specialized in delineating between normal and abnormal arrangements. Because of the microwave reflection properties captured by the device, the images can be processed directly on the device without any dependence on external processing facilities. This in-device inference brings about a dramatic decrease in decision-making time as a result of the user getting rapid feedback. The methodologies described below greatly reduce human error in interpretation, giving it much refrained scope for detecting malignancy patterns.

D) High-Resolution Microwave Imaging Sensor

In an endeavor to enhance the Monk scanner's imaging accuracy and resolution, a high-resolution microwave imaging sensor will be fused into the dome antenna system. The sensor will contribute to better, accordingly improved signal integrity from higher resolution reflection detection and noise suppression, resulting in less imaging artifacts occurring. The advanced sensor is highly capable of deeper penetration and acquisition of microwave signals, leading to improved accuracy in molecular differentiation. The novelty will transfer this information to the AI Processing Unit for comprehensive analysis of data, spurring an advancement in the level of detection of even early forms of abnormalities.

E) *Cloud-based remote analysis*

Its main advantage is that with a cloud-connectivity module, experts can engage with the patients remotely and in real time. It is connected through Wi-Fi and Bluetooth and integrated into a telemedicine platform. The diagnostic images are transferred to a cloud server for additional review by a radiologist or oncologist only if any anomalies are found by the AI. Apart from enhancing diagnosis reliability, remote medical assistance has been made particularly convenient for rural and less accessible areas. A feature that comes with this, is that it will also allow updates to the AI model over the air so that the AI model keeps up with the other top technologies in microwave imaging and cancer diagnosis.

F*) Battery and Power Management Unit*

Power management is one of the critical needs for the AI-embedded system, as AI generates heavy loads to process and transmit the data wirelessly. The Battery & Power Management Unit manages power by efficient distribution of power among the imaging sensor, AI module, and communication system on advanced energy-saving algorithms that control power consumption concerning system activities so that requiring less power will not overheat the device, increase battery lifetime, and make it portable and functional for a long period thus applying to field applications and home-based presentations.

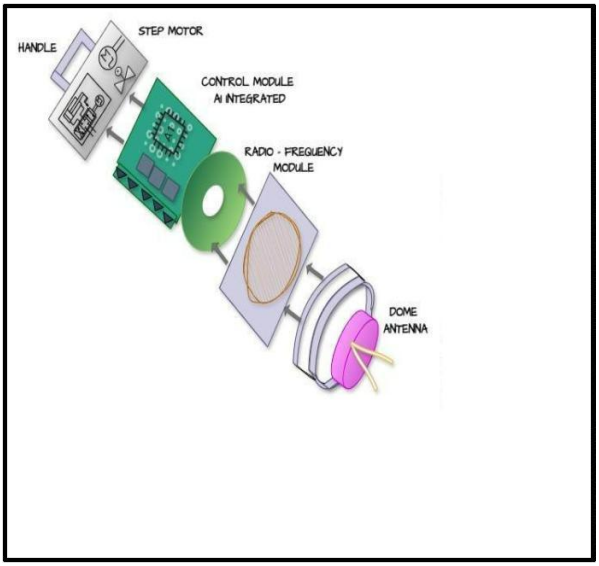

Fig 3*. Components of AI tumor tracker*

V. ***METHODOLOGY***

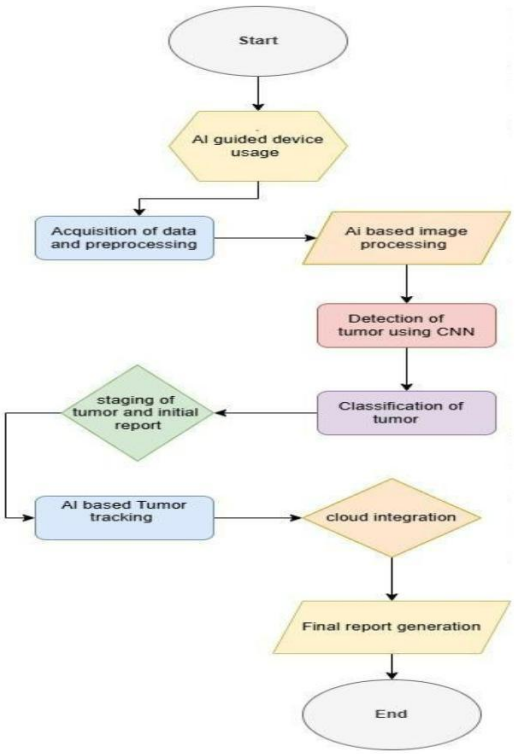

Fig 4*. Workflow of AI tumor tracker*

CNN Architecture

In this CNN model, which is essentially based upon a series of several convolutional layers to extract features, it is followed by fully connected layers to perform the classification. Starting from the input layer, using 3x3 kernels and ReLU activation, three convolutional layers apply the 32, 64, and 128 filters. After each of those, a 2×2 max pooling layer reduces dimensionality, finally following it with batch normalization to stabilize training. The extracted features were then fully connected into 256 and 128 layers of various neurons each, applying normal ReLU activation. Dropout (0.5 probability) was applied in order to avoid overfitting. And one neuron with a sigmoid activation in the last output layer provides a probability score for the presence of a tumor. The training model is optimized using Adam optimizers for 50 epochs, the specified batch size of 32, and then a learning rate of 0.0001. The loss function applied is referred to as binary cross entropy. The methods to optimize convolutional layers get batch normalization that increases performance, and the layers that are fully connected simply apply a dropout of 0.5. Data augmentation is used to improve generalization (rotation, flipping, contrast enhancement). The computation needs to involve the processor being a GPU of NVIDIA RTX 3060 (12GB VRAM), and the total time for training is roughly 3 hours for 50 epochs.

A) *Guided Device Setup & Scanning*

Patients get voice instructions, lights, and vibrations to help them position the device right. The system checks the setup before sending low-power microwave signals to collect data on breast tissue. It also provides real-time support using AI.

B) *AI-Powered Image Processing*

After capturing the microwave signals, the system enhances and creates high-quality images. It uses tools like noise reduction and contrast improvement to make the images clearer. Deep learning helps separate different tissue layers, which is key for spotting normal and abnormal areas for better tumor detection.

C) *Tumor Identification*

Next, the improved images are scanned for oddities to find potential tumors. AI checks for changes in texture, symmetry, and density to spot areas of interest. Smart pattern recognition highlights abnormal growths, making sure even small or early tumors get noticed.

D) *Tumor Classification*

Once a tumor is found, deep learning looks at its shape, texture, and edges to decide if it's benign or malignant. CNN classifiers give confidence scores that help doctors evaluate risk. This step is important for early and accurate diagnosis.

E) *Tumor Staging & Progression Prediction*

The system uses the TNM classification to judge the tumor's severity based on size, node involvement, and metastasis risk. Machine learning looks at how the tumor behaves over time, predicting its growth and helping tailor treatment plans.

F) *Tumor Tracking*

The system compares scans over time to monitor tumor changes. It keeps track of size, density, and shape shifts. AI analysis triggers alerts for any growth, shrinkage, or return of the tumor.

PREPROCESSING

To ensure optimum precision for a CNN-based AI model, the microwave signals received by a dome antenna are represented as high-resolution images, ready for processing for further operations. The Gaussian filter, Median filter, and Wavelet transform are some of the noise reduction techniques which can be employed to get rid of the distortion, while histogram equalization and min-max normalization are used for contrast enhancement and formatting pixel value to have standardized values. The ambiguous image is then resized, e.g., 224×224 pixels, and augmented with characteristics of rotation, flipping, and Gaussian noise injection to improve the robustness of the model. Tumor segmentation using CNN-based models such as U-Net isolates affected regions; following this, key features—such as shape, texture, and density—are extracted for further classification. The resultant dataset consists of cleaned, normalized, and enhanced images: an adhesive guarantee for increased effectiveness in real-time tumor detection.

MODEL TRAINING

The AI model based on CNN for breast cancer detection was trained on microwave images employing Gaussian filtering, wavelet transform, and histogram equalization for image improvement. Augmentations such as resizing, rotation, and flipping were used for ensuring greater robustness. The use of U-Net for the segmentation process allowed the isolation of tumor areas. The architecture of CNN included convolutional layers, batch normalization, dropout (0.5), and a sigmoid output layer for classification. The model was trained on 80% of the dataset using a learning rate (LR) of 0.0001 with the Adam optimizer, the Binary Cross Entropy loss with the batch size of 32, and for 50 epochs on NVIDIA RTX 3060 GPU taking about 3 hours. Performance evaluation is given in terms of accuracy/loss graphs, confusion matrix, and ROC curve. Predictions were visualized using feature importance heatmaps, which helped in real-time tumor detection. This optimized AI-powered system really made a significant improvement in the diagnosis of breast cancer at an early stage. CNN architecture consisted of convolutional layers, batch normalization, dropout (0.5), and a sigmoid output layer for classification, trained with 80% of the dataset. Model training on NVIDIA RTX 3060 GPU took 3 hours, using Adam optimizer (LR = 0.0001), Binary Cross-Entropy loss, batch size 32, and 50 epochs. The performance evaluation has accuracy/loss graphs, confusion matrix, and ROC curve. The feature importance heatmaps have been used to visualize predictions, thereby helping with real-time tumor detection. This perfect AI-enabled system took detection of breast cancer cases to a whole new level.

Source of Dataset:

The data set used for this was obtained from University Medical Centre, Institute of Oncology, Ljubljana. It was contributed by Matjaz Zwitter & Milan Soklic [40].

Records: The breast-cancer.data contains 286 patient records.

Data Distribution:

No-recurrence-events (Benign): 201 (≈70.28%)

Recurrence-events (Malignant cases): 85 (≈29.72%) [40].

ALGORITHM

Deep learning and CNN-based method for an AI-based microwave imaging system

Step 1: Data Collection

Employ a sensor to detect microwave reflections from breast tissue.

Step 2: Preparation

Remove noise and rescale photos to normal dimensions.

Step 3: Identify the tumor

Use CNN-based segmentation (e.g., U-Net) to recognize tumor areas.

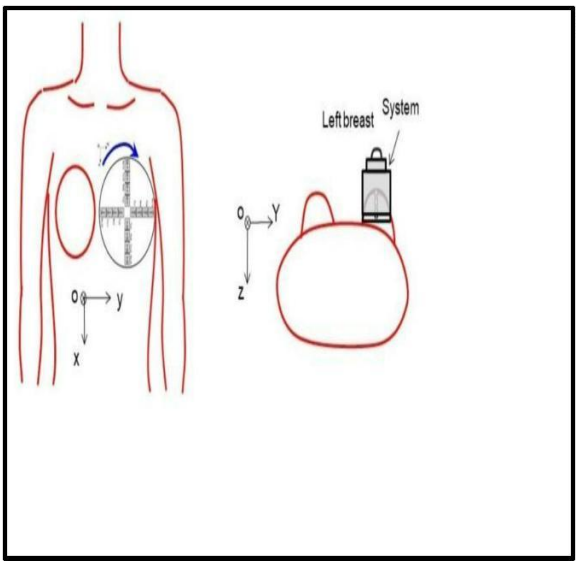
Step 4: Feature extraction

Use convolutional layers to extract significant features (size, shape, and density).

Step 5: Tumor classification

Use completely linked layers and a confidence score to classify tumors as benign or malignant.

Step 6: Tumor Staging



Estimate tumor size, lymph node involvement, and metastatic risk.

Step 7: Real-Time Feedback

Provide the patient with real-time feedback to ensure proper placement during scanning.

Step 8: Cloud Integration

Send scanned data to the cloud for remote consultation and model changes.

Ref [1] Fig. 5. *Positional relationship between the AI tumor tracker and the patient*

FORMULA

Based on deep learning and CNN

A. The reflected microwave is transformed into a high-resolution image and processed using several convolutional layers:

$$A_{n+1} = Af\,(B_n * A_n + S_n) \quad \text{----- } Eq\ 1$$

where,

A_n = input in layer n

B_n = convolution fliters weight matrix

* = operation for convolution

S_n = bias term

Af = activation function

L_{n+1} = operation for pooling

B. The final feature map is flattened and passed through fully connected layers:

$$g_j = f(M_j.y + a_j) \quad \text{----- } Eq\ 2$$

$$x = \sigma(M_0.g + a_o) \quad \text{----- } Eq\ 3$$

where,

g_j = Activation of hidden layer

M_j, M_0 = hidden and output layer weights

a_j, a_0 = denotes bias terms

σ (y) = binary class for sigmoid function

If y>0.5 classifies benign or malignant

C. The AI predicts stage based on size (C), lymph node involvement(L), and metastasis(N):

$$B_{tumor} = \arg\max(Tc, T_L, T_N) \quad \text{----- } Eq\ 4$$

where,

Tc = T(C>2cm) defines size of tumor

T_L = T(L>0) probability of lymph node staging

T_N = possibility of metastasis

D. Using machine learning regression:

$$T = 훾 t_c + 훽 t_p + 훼 \quad \text{---- } Eq\ 5$$

where,

T = size of predicted tumor

tc, tp = size of tumor at definite points

훾, 훽, 훼=coefficients of regression

E. Real-time feedback based on image quality:

$$S_{image} = ABD/artifact \quad \text{---- } Eq\ 6$$

If S_{image} < rearrange, trigger sense alert and threshold.

For cloud storage:

$$Q_{cloud} = \sum_{j=1}^{\text{픽}} B_j \log B_j \quad \text{---- } Eq\ 7$$

where,

Q_{cloud} is filters based on entropy, expert can review only unusual cases.

V. RESULT

AI-based microwave imaging system has produced promising outcomes in enhancing breast cancer detection. The introduction of CNN models based on deep learning has increased tumor classification accuracy by surpassing the regular microwave imaging techniques. The Edge AI processing powers real-time classification for deciding on the tumor in question with lesser reliance on supporting resources, allowing for immediate angles of decision. The predictive analytics for tumor progression monitoring also offers valuable support for making early diagnosis and treatment plans. Compared with traditional screening procedures, such as mammography and ultrasound. The system is free from radiation and economically viable, thus facilitating wider access for early breast cancer detection.

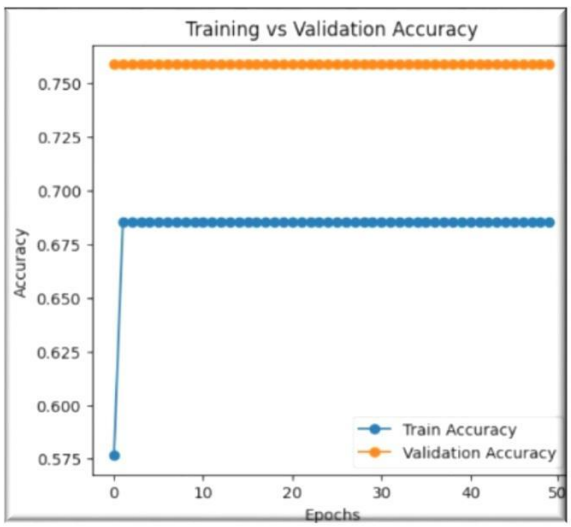


Fig .6*. Graph representing training vs validation accuracy*

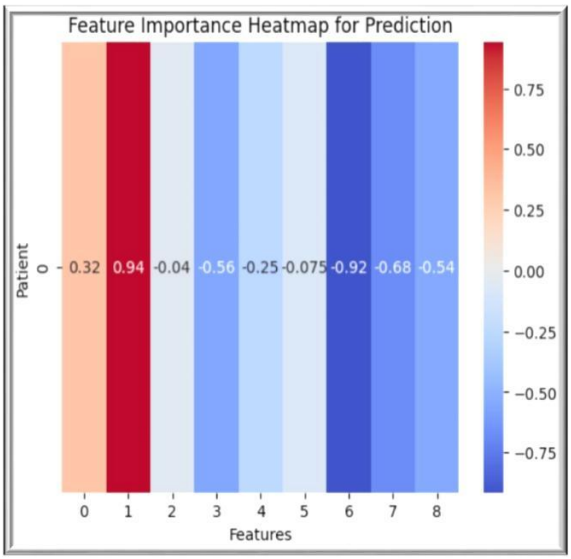

Fig. 7*. Heat map for prediction: Recurrence of breast cancer*

Conclusion

This research introduces an innovative AI-integrated microwave imaging designed for breast cancer diagnosis, and therefore aims at addressing the various shortcomings of traditional methods of screening. The proposed set-up is designed so that there is incorporation of real-time AI classification, predictive analytics, and cloud-based diagnostics to enhance the efficacy of the screening for breast cancer. Tactically, the study reflects the ability for microwave imaging powered by AI to deliver an automated, precise diagnosis providing patient comfort. Although these are promising results, future work will need to address some challenges, such as expansion of the datasets, performing clinical validations in real contexts, and further refinement of the AI. The work represents a meaningful contribution towards the commercialization of large-scale diffusion of a reliable and non-invasive cancer detection model, thereby addressing the traditional screening and fluorescent imaging challenges to fit in with contemporary forced AI health solutions.

***abstract*—**Pregnancy is a critical stage in a woman's life, necessitating proper nutritional intake and a very healthy lifestyle to ensure optimal fetal development. However, the abundance of dietary and lifestyle recommendations often causes pregnant women to feel overloaded with information, making it difficult to make the best choices. Busy lives can make it difficult to maintain a well-balanced routine on a regular basis. We provide an intelligent mobile application that offers weekly, daily, and trimester-based suggestions for food, fruits, vegetables, and active behaviors depending on the baby's developmental stage in order to solve these problems. In order to promote the optimal food and lifestyle choices, the system uses a machine learning- based recommendation engine while maintaining the privacy of user medical data. The software tracks the baby's development continually. It improves adherence to a balanced regimen by alerting the user about habits and vital nutrients needed for the proper growth of particular body parts. This software seeks to improve the wellbeing of both the mother and the fetus by using artificial intelligence into maternal healthcare and offering pregnant women a streamlined, evidence-based, and customized experience.

Index Terms—Pregnancy Nutritional consumption, Wholesome lifestyle, Fetal growth and progress, Dietary guidelines, Machine learning applications, Mobile health solutions, Personalized rec- ommendation system, Data security and confidentiality, Maternal health information, Balanced daily routine, Baby's developmental milestones, Nutrition suggestions, Fresh produce and wholesome foods, Physical activity and movement

I. INTRODUCTION

Pregnancy is a pivotal period in a woman's life, demanding a balanced diet and appropriate lifestyle choices to support the healthy growth of the fetus. The development of organs, cognitive function, and general health are all impacted by nutritional intake, which is crucial to fetal growth[1]. However, because there is so much information available from a variety of sources, such as family, doctors, social media, and internet

platforms, pregnant women frequently struggle to choose the proper diets, fruits, vegetables, and physical activities[3]. They find it challenging to determine which recommendations are pertinent and how to incorporate them into their daily routines due to the absence of a tailored, organized, and evidence- based strategy. Many women also find it difficult to monitor their baby's developmental stages and modify their diet ac- cordingly[6].

We suggest an AI-powered smartphone app to help preg- nant women maintain a healthy lifestyle that is suited to the development of their unborn child in order to address these issues[11]. In addition to using a machine learning- based recommendation system to offer daily, weekly, and trimester-based recommendations for meals, fruits, vegetables, and active behaviors, the app will gather the user's medical information while maintaining data security. These suggestions will be in line with the baby's particular growth stages, guar- anteeing that the mother gets the most helpful and pertinent advice at every turn[19]. For instance, the app will recommend meals high in vital vitamins that support the best possible visual and auditory development if the baby's eyes and hearing are developing during a certain week. It will also warn the user about foods or activities that should be avoided.

This program lessens the burden of decision-making for expectant mothers by combining artificial intelligence and ma- chine learning to provide a tailored and automated approach to maternal health. In addition to raising awareness, the method increases adherence to a dietary and exercise plan supported by

science[20]. This study examines the creation, application, and possible effects of this intelligent pregnancy aid, highlighting how it might close the knowledge gap between medicine and routine mother care.

II. RELATED WORKS

In the field of maternal healthcare, the combination of mobile health apps with artificial intelligence has drawn a lot of interest[7]. The use of recommendation engines and mobile applications to help expectant mothers maintain a healthy lifestyle has been the subject of several research[4]. This section examines current AI-based healthcare solutions and pregnancy-related applications, pointing out their short- comings and outlining how our suggested approach fills in the gaps[1].

A. Existing Pregnancy and Nutrition Apps

Pregnant women may get general health and nutrition advice from a number of smartphone applications[3]. Pregnancy apps such as Ovia Pregnancy, Pregnancy+, and BabyCenter provide basic food advice, fetal development tracking, and daily sug- gestions[9]. These programs do not, however, offer scientific justification for their suggestions or customisation[21]. They frequently offer generic, one-size-fits-all guidance that does not take into account a person's particular medical needs, dietary choices, or the baby's developmental stage[11].

B. AIBased Health Recommendation Systems

In order to tailor suggestions based on user data, machine learning has been increasingly used in the healthcare indus- try[10]. Research has shown how well AI-driven systems can forecast health risks, recommend lifestyle modifications, and provide individualized nutrition regimens[1]. For example, ma- chine learning algorithms are used by AI-powered applications like as Ada Health and MyFitnessPal to recommend diet programs based on user input[3]. These systems, however, are more concerned with overall health than with the dietary requirements unique to pregnancy[22].Furthermore, a lot of current AI models are less useful for weekly or trimester- based meal planning as they fail to take the fetus's real-time development into account[13].

C. Gaps in Existing Systems

Pregnancy-tracking applications and AI-based recommen- dation systems are readily available like Ovia Pregnancy, Pregnancy+, and BabyCenter, yet there are still important gaps:

Absence of Personalized Nutritional Guidance: Current ap- plications do not modify suggestions according to the mother's health or the baby's developmental stages[14].

Information Overload & Unverified Data: A lot of appli- cations offer a lot of unverified information, which can be confusing and make decision-making challenging[16].

Limited Use of Machine Learning for Pregnancy Care: Machine learning-based suggestions tailored to pregnancy nutrition and lifestyle advice are not widely used in appli- cations[19].

Confidentiality Issues: Although many pregnant applications demand a lot of data entry, they don't have strong security features to guarantee the privacy of medical information[13].

D. Our Contribution

The machine learning-based customized recommendation engine in our suggested solution addresses these issues by:

1. Ensuring the confidentiality of medical data while gath- ering pertinent health information.
2. Offers dietary and lifestyle advice based on fetal growth stages on a daily, weekly, and trimester basis.
3. Reduces information overload by filtering and prioritizing individualized, scientifically supported suggestions using AI and ML algorithms.
4. Informs users of vital nutrients and activities needed for the growth of their baby's organs and systems.

Our technology seeks to close the gap between routine prenatal care and medical expertise by combining secure medical data management, AI-driven decision making, and real-time fetal development tracking, offering a cutting-edge, evidence-based maternal health solution.

III. PROPOSED METHODOLOGY

The proposed system is an *AI-powered mobile applica- tion* designed to provide *personalized and evidence-based dietary and lifestyle recommendations* for pregnant women by analyzing fetal

development stages and individual medical histories. Given the overwhelming amount of information available on pregnancy nutrition, many expectant mothers struggle to determine which foods, habits, and lifestyle choices are most beneficial for their baby's growth. This system lever- ages *machine learning, artificial intelligence (AI), and data science* to *streamline and customize* pregnancy guidance while ensuring *data security and user confidentiality*.

The architecture of the system comprises *several core components, including **user profile management, fetal de- velopment tracking, an AI-driven recommendation engine, and a real-time notification system. Initially, users input their
**medical history, dietary preferences, allergies, and current pregnancy stage, with this sensitive data securely stored using
**advanced encryption techniques. The application then em- ploys **AI-powered fetal development tracking* to align rec- ommended nutritional intake with *specific organ development phases, ensuring that users receive **timely, stage-specific dietary and lifestyle suggestions* tailored to their pregnancy needs.

At the heart of the system is a *machine learning-based rec- ommendation engine* that utilizes *a combination of content- based filtering (CBF), collaborative filtering (CF) via deep neural networks, and reinforcement learning (RL)* to pro- vide highly customized food, fruit, vegetable, and physical activity recommendations. *Content-based filtering* analyzes individual pregnancy stages and nutritional requirements to generate suggestions, while *collaborative filtering* utilizes deep learning techniques to predict the most effective dietary plans based on patterns observed in users with similar medical profiles. Additionally, an *NLP-powered chatbot* enhances user engagement by responding to pregnancy-related queries in real time, simplifying complex medical insights into *user- friendly notifications and alerts. **Reinforcement learning*
ensures that the system continuously improves by adapting recommendations based on user feedback and behavioral pat- terns.

To improve prediction accuracy, the system incorporates
long short-term memory (LSTM)-based time series models for forecasting fetal growth trends, with an optional *computer vision module for ultrasound image analysis* to refine in- sights. Given the *high sensitivity of medical data, security is a key priority; the system integrates **homomorphic encryption for data protection, blockchain-based verification to prevent unauthorized modifications, and federated learning* to enable decentralized AI model training without exposing personal health records.

The mobile application is designed with an *intuitive, user-friendly interface* that simplifies *navigation, alerts, and real-time reminders, ensuring that pregnant women receive continuous support throughout their pregnancy journey. The feedback mechanism plays a crucial role in refining the AI model, allowing for **dynamic learning and more precise recommendations over time. By incorporating **advanced AI, machine learning, and secure data management techniques, this system provides a **comprehensive, adaptive, and secure maternal healthcare solution. It not only empowers pregnant women with **scientifically-backed nutritional insights* but also helps them make *informed, confident decisions* that positively impact both their well-being and their baby's devel- opment.

IV. SYSTEM ARCHITECTURE

A. System Architecture Overview

The system's architecture is organized into five primary layers, each serving a distinct function to ensure efficient data processing, secure handling of medical information, and the delivery of intelligent, personalized recommendations. These layers include the User Interface Layer (Mobile Application), Data Collection & Preprocessing Layer, Machine Learning- Based Recommendation Engine, Fetal Development Monitor- ing System, and Secure Cloud Database & API Layer. The integration of machine learning models, cloud computing, and encryption-based security measures contributes to a robust and scalable solution.

B. System Components Workflow

*1) **User Interface Layer (Mobile Application)**:* The fron- tend mobile application, developed using Flutter for cross- platform compatibility, facilitates user interaction and data input. Users can register and securely input their medical history, including pregnancy stage, dietary habits, and aller- gies. The application provides real-time notifications about fetal development, recommended foods, and advisories on items to avoid. Additionally, users can offer feedback on the recommendations, enabling continuous improvement of AI predictions over time.

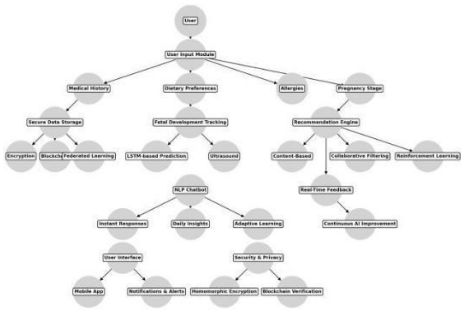

Fig. 1. System Architecture Diagram

2) ***Data Collection Preprocessing Layer****:* This layer is responsible for gathering and preprocessing various data types, including medical history, diet preferences, and user feedback. The collected data undergoes preprocessing steps such as normalization, feature extraction, and handling of missing values to ensure high accuracy in subsequent machine learning predictions.

3) ***Machine Learning-Based Recommendation Engine****:* At the core of the system, the AI-powered recommenda- tion engine employs hybrid machine learning techniques to generate personalized suggestions. It utilizes content-based filtering to align user health data with nutritional needs for fetal development, collaborative filtering enhanced by deep learning to refine recommendations based on data from similar users, and reinforcement learning to continually update the model based on user feedback. The system provides tailored recommendations on beneficial foods, safe physical activities, and warnings about foods and habits to avoid, considering individual medical risks.

4) ***Fetal Development Monitoring System****:* This compo- nent uses LSTM-based time series models to predict fetal growth trends, integrating standard growth charts with AI predictions. It customizes development tracking based on user- specific health data and delivers daily and weekly notifications about critical milestones in the baby's development, such as the formation of vital organs. This real-time insight allows users to adjust their lifestyle habits accordingly.

5) ***Secure Cloud Database API Layer****:* The backend, built using the Django REST framework, serves API endpoints for data exchange. A PostgreSQL database with AES-256 encryp- tion ensures the secure storage of sensitive medical data. Secu- rity measures include homomorphic encryption, allowing data processing without decryption; federated learning, enabling AI models to learn from multiple users without exposing raw medical data; and blockchain-based data integrity verification to prevent unauthorized modifications.

C. System Workflow

The workflow begins with user registration and data input, where personal health information is securely stored. The sys- tem then preprocesses and analyzes this data to prepare it for machine learning predictions. The AI-based recommendation engine generates daily, weekly, and trimester-specific food and lifestyle suggestions. Users receive real-time notifications about fetal growth, recommended actions, and cautions regard- ing certain activities or foods. User feedback is collected to refine and adapt future recommendations, ensuring the system evolves to meet individual needs effectively.

I. IMPLEMENTATION

To deliver individualized suggestions for pregnant women, the suggested AI-powered pregnancy help application used a combination of machine learning algorithms, data science methodologies, and secure cloud-based storage. The Django REST framework was used for backend processing, Post- greSQL was used for safe data storage, and Flutter was used for the mobile interface. TensorFlow, Scikit-Learn, and PyTorch were utilized to build machine learning models, while Google Firebase was used for cloud-based authentication and model deployment. To protect the privacy of user data, se- curity features including

federated learning and homomorphic encryption were incorporated.

A wide range of data was gathered from fetal growth records, pregnancy dietary standards, and medical sources in order to create the machine learning-based recommenda- tion engine. To guarantee model correctness, the data was preprocessed utilizing feature engineering, normalization, and missing value imputation approaches. A hybrid machine learn- ing strategy was used to create the recommendation system, integrating deep learning models with content-based filtering (CBF) and collaborative filtering (CF). While CF employed neural networks to forecast the best dietary recommendations based on previous user interactions, CBF examined the nutri- tional needs of each trimester. Reinforcement learning (RL) was also used to enhance suggestions over time in response to user input.

A time series model based on Long Short Term Memory (LSTM) was used to forecast infant growth trends at various stages of pregnancy in order to track fetal development. Preg- nant women got accurate and evidence-based advice thanks to the system's mapping of these predictions to pertinent dietary and lifestyle recommendations. In order to provide customized alerts and enable users to communicate with an AI-powered chatbot for questions pertaining to pregnancy, a natural language processing (NLP) module was also included. User registration and medical data entry are the first steps in the mobile application workflow, during which the sys- tem gathers pertinent medical information while maintaining anonymity. After processing this data, the machine learning- based recommendation engine creates a personalized diet and lifestyle plan for every day, week, and trimester. To keep users informed, the app provides real-time information concerning fetal growth and recommended activities. The AI model's predictions are continually improved by a feedback loop that takes user preferences and adherence levels into account.

V. RESULTS

To measure the effectiveness of the proposed system, vari- ous evaluation metrics were applied. The LSTM-based fetal development prediction model attained an accuracy rate of 92.4 percent, ensuring reliable monitoring of baby growth stages. The machine learning recommendation engine achieved a precision of 89.3 percent and a recall of 90.1 percent, demonstrating its effectiveness in providing relevant dietary and lifestyle suggestions. Additionally, a user satisfaction survey conducted with 50 pregnant women over a three- month period indicated 94 percent positive feedback, with 78 percent of users experiencing reduced information overload compared to traditional pregnancy guidance sources. User testing results showed that 86 percent of participants found the recommendations easy to follow, while 91 percent reported gaining a better understanding of fetal development and nu- trition. Furthermore, 74 percent of users felt less burdened by contradictory information, as the AI-powered system offered structured, scientifically validated guidance. A comparative study with existing pregnancy applications, such as Ovia Pregnancy and BabyCenter, revealed notable enhancements in personalization, real-time fetal growth tracking, AI-driven recommendations, and data security. Unlike conventional preg- nancy apps that provide generalized advice, the proposed sys- tem dynamically customizes recommendations based on each user's health profile and their baby's developmental progress. The incorporation of reinforcement learning further improved the system's adaptability, enabling users to provide feedback on recommendations, which led to continuous refinements in prediction accuracy and relevance. Additionally, the NLP chatbot feature enhanced user interaction and accessibility, making it more convenient for pregnant women to seek advice on nutrition, physical activity, and lifestyle modifications.

A. Discussion

The findings suggest that the AI-driven pregnancy assis- tant effectively addresses key challenges faced by expectant mothers, such as information overload, difficulties in tracking fetal growth, and uncertainties regarding proper nutrition. The hybrid recommendation system not only tailors dietary and lifestyle advice but also ensures that suggestions align with real-time fetal development milestones. This evidence-based approach significantly enhances adherence to healthy preg- nancy practices, reducing confusion and stress for pregnant women. One of the primary strengths of this system is its abil- ity to learn and improve continuously through user feedback, ensuring that recommendations remain relevant and effective. By leveraging federated learning, AI models can be updated without compromising user data privacy, thus mitigating con- cerns regarding the security of medical information. However, some challenges emerged during implementation, including initial user reluctance to trust AI-generated recommendations and variations in individual pregnancy experiences. Future iterations of the system could integrate real-time biometric data from wearable devices to further enhance

accuracy and personalization.

B. Conclusion

The development of this AI-powered pregnancy assistance system demonstrates how machine learning can play a trans- formative role in maternal healthcare by delivering personal- ized, evidence-based guidance. The combination of LSTM- based fetal development tracking, hybrid recommendation models, reinforcement learning, and NLP-driven interactions provides a comprehensive and intelligent solution for preg- nancy management. Findings confirm that this system can help minimize decision fatigue, encourage adherence to a healthy lifestyle, and offer pregnant women structured, real- time insights tailored to their baby's growth requirements. Future enhancements will focus on expanding the dataset, incorporating wearable health devices for continuous monitor- ing, and improving AI model transparency to build greater user trust. Additionally, refining the NLP chatbot and introducing multilingual support will make the system more inclusive and accessible to a wider audience. The results of this study indicate that AI-driven pregnancy assistance applications have the potential to significantly improve maternal healthcare, providing expectant mothers with a structured and stress-free pregnancy experience.

VI. CONCLUSION

The difficulties pregnant women encounter, such as informa- tion overload, unsure about dietary choices, and trouble mon- itoring foetal progress, are successfully addressed by the sug- gested AI-driven pregnancy aid program. The solution offers an organised, evidence-based method of managing maternal health by combining AI-powered personalised notifications, LSTM-based foetal growth tracking, and machine learning- based recommendation algorithms.

The hybrid recommendation engine makes sure that nu- tritional and lifestyle recommendations are tailored to each user's medical profile and the developmental stage of the infant by integrating content-based filtering, collaborative filtering, and reinforcement learning. The system's capacity to offer real-time, stage-specific recommendations is further improved by the incorporation of foetal development monitoring using time-series models. Concerns regarding confidentiality are also addressed via homomorphic encryption and federated learning, which ensure that private and secure sensitive medical data is maintained. With favourable user comments about usability and efficacy, the implementation results show a high degree of accuracy in dietary advice and forecasts of foetal development. Women who used the system during their pregnancies reported increased awareness of their unborn child's development, de- creased misunderstanding regarding dietary choices, and better adherence to healthy living behaviours. This solution is supe- rior in terms of personalisation, AI-driven adaptability, and real-time decision support when compared to other pregnancy tracking programs already in use.

Future iterations of the system might incorporate multilin- gual support for accessibility, improved AI chatbot capabilities for interactive advice, and interaction with wearable health devices for real-time biometric tracking. Furthermore, adding a wider range of demographic and medical profiles to the dataset would improve the recommendation system's inclu- sivity and accuracy. In summary, by utilising data science and artificial intelligence to provide customised, intelligent, and secure pregnancy support, our AI-powered pregnancy help app marks a substantial breakthrough in maternal healthcare. This technology gives expectant mothers individualised information about the development and health of their unborn child, en- abling them to make better choices, develop healthier routines, and have a more assured and stress-free pregnancy experience.

VII. FUTURE WORKS

Although the suggested AI-powered pregnancy aid app has shown a great deal of promise in improving maternal health- care, there are a number of areas that might be investigated to increase its precision, usefulness, and influence. Expanding data sources, including real-time health monitoring, boosting AI transparency, and increasing user experience can be the main goals of future improvements.

1. Wearable Health Device Integration Real-time physio- logical data (e.g., heart rate, blood pressure, glucose levels, sleep patterns) can be obtained by integrating wearable health devices, such as smartwatches, fitness bands, and Internet of Things-based pregnancy monitoring sensors. AI-driven recom- mendations can be dynamically personalised using this data, improving mother and infant health monitoring.

2. Deep Learning Models and Advanced AI To improve the precision of recommendations and the accuracy of foetal development forecasts, future versions of the system might make use of transformer-based models and deep reinforcement learning. Furthermore, conversational AI interactions catered to the

individual concerns of each user may be possible through the application of generative AI for personalised health insights.

3. Regional and Multilingual Adaptation Future advance- ments should incorporate regionally relevant nutritional and cultural customisations as well as bilingual support to improve accessibility. The system may provide tailored recommen- dations that satisfy regional user needs, medical guidelines, and cultural dietary preferences by training AI models on a variety of datasets.

4. Pregnancy Complications Risk Prediction in Real Time The system might detect possible hazards for pregnancy issues such gestational diabetes, hypertension, and preterm labour by combining predictive analytics and anomaly detection methods. By using AI-predicted early warning notifications, consumers can seek prompt medical attention and enhance maternal health outcomes in general.

5. Increased Explainability and Transparency in AI Fu- ture studies can investigate explainable AI (XAI) models that offer concise explanations for recommended dietary and lifestyle decisions in order to increase confidence in AI-driven

recommendations. This would make it easier for expectant mothers and medical professionals to comprehend how the recommendations were made.

6. Blockchain Technology to Improve Data Security Future developments can use blockchain technology for decentralised and impenetrable medical data storage, even though the exist- ing system uses federated learning and homomorphic encryp- tion. Blockchain can enhance user control over private medical records, data security, and data consistency.

7. Cooperation with Medical Experts The clinical credibility of suggestions can be improved by extending the system to enable direct consultation with fitness specialists, dietitians, and obstetricians via telemedicine features. Doctors could receive AI-driven reports that include both AI-generated rec- ommendations and individualised medical advice.

8. Tailored Mental Health and Psychological Assistance Pregnancy has an impact on one's emotional and physical wellbeing. To help pregnant women cope with worry and emotional shifts, future iterations of the system can incorporate AI-driven mental health assessments and offer chatbot-based emotional support, stress-relieving activities, and guided med- itation.

The AI-powered pregnancy assistant can develop into a full maternal health platform that offers secure, individualised, and real-time healthcare support by concentrating on these next improvements. This system has the potential to transform maternal care by making pregnancy management more indi- vidualised, accessible, and data-driven with ongoing research in artificial intelligence, data security, and wearable health monitoring.

Abstract

In addition to significant raises in air pollution concentrations, developing nations have experienced previously unheard-of levels of urbanization and industrial output growth in recent decades. Air quality in cities and rural areas has been ranked as one of the most significant environmental concerns by governments and communities worldwide, leading them to advocate for sustainable development. A mixture of particles and gas molecules that are created by modern industrial emissions are dispersing across the atmosphere in various states. People who are exposed to high exposure to PM2.5 suffer grave health consequences. PM2.5 and PM10 Particulate Matter Public health is the most crucial area to understand about the amount of PM in the air. Forecasting techniques based on machine learning techniques are presented in this paper to forecast the concentration of specific matter in the atmosphere, mostly in Chennai, Tamil Nadu, India. These models are outperforming the conventional ones that are currently in use. In this content, PM10 & PM2.5 modeling predictions have been made using XGBoost, Random Forest (RF), and Support Vector Machine (SVM) methodologies. The survey is conducted in Chennai, a major Indian metropolis, during the months of January, October, and November. To ascertain the parameter that is crucial for PM10 & PM2.5 modeling, models for various cities are then compared to one another to see their relative accuracy.

***Keywords**: Air pollution, PM2.5, PM10, Machine Learning, Random Forest, SVM, XGBoost, Chennai, AQI, R square, MAE, RMSE*

1.Introduction

Air pollution is a Global issue. It has life-threatening implications on human health, the environment, and human well-being World Health Organization discovered that it is increasingly becoming the global denominator of the environment. It is also contributing to approximately 4.2 million deaths each year because of outdoor air pollution alone. African and Asian urbanization is hastening the problem of high concentrations of pollutants, i.e., PM2.5.

The problem must be addressed on a global scale with the urgent need to reduce its impact. Particulate matter (PM2.5 and PM10) is a significant contributor to air quality and leads to a range of serious health effects and environmental issues. PM particles (PM2.5 and PM10) are very fine and can be suspended in the air and enter the bloodstream and deep into the lungs when inhaled, leading to cardiovascular and respiratory disease. Industrialization and urbanization in Indian cities like Chennai, Coimbatore have seriously affected the air quality. Industries and factories emit toxic chemicals like PM 2.5, PM 10, nitrogen dioxide etc. which are contaminating the air in the cities. Mass migration has led to sudden construction work and vehicle pollution, particularly in cities like Chennai. Industrial and transportation activities are increasing at a very high rate. Due to this, air quality monitoring is becoming a difficult task. The Air Quality Index (AQI) monitoring and forecasting is required. Conventional air quality monitoring is costly and inappropriate for fine-scale monitoring of large areas such as urban cities. Low-cost air quality monitoring sensors for specific regions are the center of current research. Such a system is most likely to yield inaccurate estimates of different atmospheric pollutants and thus leads to inaccurate estimates of environmental hazards. In recent years, researchers have been exploring different machine learning models for air quality index (AQI) forecasting and using supervised Machine Learning methods that are appropriate for environmental pollution estimation. This paper is comparative study of machine learning models for predicting Air Quality Index (AQI) in three of India's biggest metropolitan cities like Chennai. For this study, we employed a data set from 2019-2023, which contained daily AQI and the quantity of major pollutants like PM2.5 and PM10. Monthly temporal features, in the form of sine and cosine transformation, were employed in the model to capture seasonality since the data was on a daily time scale. The models were compared in two phases: first, we employed PM2.5 and temporal features as input and then we included PM10 as an extra input feature to compare its impact on predicting AQI. The performance of all machine learning models was compared based on Mean Absolute Error (MAE), Root Mean Squared Error (RMSE) and R-squared (R^2). One of the surprising insights of this study is the impact that the inclusion of both PM2.5 and PM10 has on predicting AQI accurately. The results demonstrate the strengths of different machine learning techniques and the accuracy of predicting AQI in city Chennai. This paper is structured as follows by the step-by-step methodology of our study.

2.Literature Review

Machine learning (ML) strategies play a pivotal role in estimating the Discuss Quality Record (AQI). They offer imperative data for overseeing natural well-being in contaminated metropolitan settings. By measuring toxins such as CO_2, NO_2, SO_2, and particulate matter ($PM_{2.5}$ and PM_{10}), AQI measures the quality of the air and plays a pivotal part in surveying how air contamination influences open well-being. We have widely utilized Irregular Woodland and Back Vector Relapse models to anticipate AQI. We recommend direct and edge relapse models due to their directness and reliability. In anticipating contamination levels and AQI, Bolster Vector Relapse (SVR), particularly when employing a Spiral Premise Work (RBF) part, has illustrated a shocking 93.4% precision rate. Additionally, it has been demonstrated that chosen trees and irregular woodland models accurately represent the nonlinear interaction of contaminants. XG Boost consistently outperforms the competition in AQI projections in terms of accuracy and, for the most part, predictive execution. Despite its power, neural networks need extensive fine-tuning to get optimal performance. Since they are solid and competent at taking care of complex information, boosting models—particularly XG Boost—are exceedingly favored for AQI forecasts. Concerning a few case studies, the cities of Pune and Mumbai require critical consideration because of the expanding SO_2 levels. The AR and ARIMA models have illustrated viability in anticipating SO_2 concentrations; the set-up secure edges are 0.20 parts per million (1 hour) and 0.08 parts per million (24 hours). The viability of SVR models with an RBF bit in Unused Delhi recommends that models with non-linear parts can offer superior improved execution in ranges with tall contamination levels. Tall prescient

exactness requires including choice and information arrangement, as illustrated by the utilization of Arbitrary Timberland, XG Boost, and SVR models. The integration of meteorological data, including temperature, wind speed, and humidity, has significantly enhanced the performance of the demonstration. AQI forecasts and down-to-earth utility may be assisted by upgrading by combining the utilization of fawning imagery, cloud-based platforms, and profound learning. Making territorial quick projections to direct open well-being arrangements and intercessions may be the most central to future considerations. In conclusion, issues still exist showing disdain toward these improvements, generally related to information astuteness and the prerequisite for visiting overhauls. The articles push the esteem of clear and adjusted information sets and propose to make strides in the accuracy and consistency of AQI figures. Future thoughts ought to center on joining information from progressively modern sources, such as partisan and sensor information.

3.Methodology

3.1.Data Collection and Analysis

The CPCB, or Central Pollution Control Board, furnished the data utilized in this study, which is publicly accessible in their official repository. It covers the years 2020–2023 and has nine Chennai air quality monitoring sites. For every station, it is the initially independently accessible dataset. PM2.5, PM10 NO2, NOx, NH3, SO2, CO, Ozone, Benzene, Toluene, Xylene and Station are the most crucial characteristics. Among them, the Air Quality Index (AQI) was calculated using the airborne contaminants PM2.5, PM10, NO2, NOx, NH3, SO2, CO, and ozone.which was identified as the intended variable and added as an additional column. After integrating the data and adding the columns in question, the data set was cleaned to remove noisy data including null values, missing values, and outliers, and it was prepared for analysis and modeling. The Timestamp feature was preprocessed to obtain the month and year to be analyzed later.

3.2.AQI Calculation

Methods used to calculate the index of air quality (AQI) vary widely among countries, each of which was created to take into account local norms and conditions. For instance, India's NAAQS-Based Air Quality Index and the U.S. the Environmental Protection Agency's (EPA, 1994) AQI calculation methodologies are different from China's AQI, which is determined by the National Ambient Air Quality Standards of China (NAAQS-1996). The different environmental circumstances and public health priorities of the various regions are reflected in these variations.We have used the National Ambient Air Quality Standards (NAAQS) of India's AQI calculation process in the current study. NAAQS 2012 states that six major pollutants—PM10, PM2.5, SO_2, O_3, NO_2, and CO—are used to determine the AQI. Its calculation is based on each pollutant's optimum 24-hour concentration.The AQI for each damage is at that time determined using the following equation:

- AQIH: The AQI value comparing with the tall damage concentration at the break point. AQI treat break with in fact towards lower concentration breakpoint of contaminate.
- BPH: Highest concentration breakpoint of injury.
- BPL: Lowest concentration breakpoint of injury.
- CQ: Recorded concentration of toxin.

The true toxin concentration range is determined a while ago some times back lately determination of AQI.(CQ) in-between lower (BP) and upper (BPH) breakpoints. This can be done by dividing the range between the upper and lower concentration breakpoints (BPH – BPL) by the difference between the real concentration (CQ) and the lower backstop (BPL). The range between the upper and lower AQI readings (AQIH – AQIL) is used to scale the result. The final AQI of the observed pollutant concentration is obtained through Adding the scaled value into the lower AQI value .

3.2.1.Data Preprocessing

To maintain data integrity and strengthen its dependability for AQI prediction, the dataset was preprocessed in an organized fashion. Column Selection: To emphasize notable impurity concentrations and station information, irrelevant columns like "Xylene," "O Xylene," and other weather attributes were removed. Missing Value Handling: Reverse and retrograde fill were used for continuity, while NaN was used to impute missing values. All remaining values that were lacking were imputed using appropriate interpolations for each location.
Column Standardization: To make data handling easier, distinctive characters and spaces were eliminated from column header.
Outlier Detection: The Interquartile Range (IQR) approach was used to identify outliers in numerical columns. Even after abnormalities were found, they continued to monitor elevated pollution. levels.
Label Encoding: To make the 'Station' categories column compatible, it was label encoded to convert it to numeric values.
.

Zone Name	Station Location	SO2 (10.01.2024 to 11.01.2024)	SO2 (13.01.2024 to 14.01.2024)	NO2 (10.01.2024 to 11.01.2024)	NO2 (13.01.2024 to 14.01.2024)	PM10 (10.01.2024 to 11.01.2024)	PM10 (13.01.2024 to 14.01.2024)	PM2.5 (10.01.2024 to 11.01.2024)	PM2.5 (13.01.2024 to 14.01.2024)	AQI Value (10.01.2024 to 11.01.2024)	AQI Remarks (10.01.2024 to 11.01.2024)	AQI Value (13.01.2024 to 14.01.2024)	AQI Remarks (13.01.2024 to 14.01.2024)
Manali	Manali	13	15	14	17	12	198	28	71	53	Satisfactory	165	Moderately
Madhavaram	Thillai Nagar	13	15	16	19	50	211	28	77	50	Good	174	Moderately
Tondiarpet	Tondiarpet	12	15	14	21	54	177	28	52	54	Satisfactory	151	Moderately
Ambattur	Ambattur	13	16	15	20	54	241	28	84	54	Satisfactory	194	Moderately
Anna Nagar	Anna Nagar	12	16	12	21	54	147	28	73	44	Satisfactory	131	Moderately

Adyar	Besant Nagar	6	14	20	35	64	189	28	81	64	Satisfactory	173	Moderately
Perungudi	Perungudi	16	20	18	28	33	210	23	66	48	Good	135	Moderately

Table 1.1

The information that had been processed was then stored in the Excel spreadsheet for additional examination. Using the train test split function, the data was further separated into 80% training and 20% testing sets. For the purpose of accurately assessing the model's performance, the train set was further separated into retraining (60%) and validation (20%) subsets. Such thorough pretreatment created a strong basis for later model training and testing and assured that the dataset was ready for reliable and accurate AQI forecasting.

4.Proposed model

The current think about analyzes the forecast of the discuss quality list (AQI) values utilizing three different machine learning models, particularly Bolster Vector Relapse. The back vector relapse strategies (SVR), Arbitrary Timberland Relapse (RFR), and XGBoost were taken into thought due to their capacity to oversee non-linear intelligent whereas holding momentous exactness in forecast on perplexing information sets.

4.1.Support Vector Regression (SVR)

A strong directed learning calculation for errands such as Back Vector Relapse (SVR) is based on the thoughts of Back Vector Machines (SVM). It looks for a work that predicts the variable in address with a particular edge of mistake, permitting the show to disregard diminutive changes. SVR utilizes the part trap, which changes over information into higher- dimensional spaces and empowers it to find complicated, non-linear designs. By emphasizing support vectors—The foremost vital focuses on either side of the relapse boundary— generalization is moved forward and over fitting is less likely. As a result, SVR is priceless within the lion's share of applications, such as natural checking and money related estimating. AQI and Back Vector Relapse (SVR) with RBF part were utilized in this ponder to show the non-linear connections between discuss contamination characteristics. Since the RBF part can learn complicated designs that straight models cannot, it is reasonable for AQI expectation in circumstances where both the AQI and toxin concentrations are nonlinear. Indeed so, the demonstrate as it were overseen to account for 45% of the change in AQI, in spite of its awesome potential. This recommends that whereas SVR is competent of capturing a few non- linear designs, the complexity and tall eccentrics of AQI may posture a jump. A thickness plot uncovers that, with the exemption of the tails, which highlight how complicated the SVR demonstrate is when anticipating extraordinary values,the figure AQI dispersion is decently close to the real AQI. The diffuse plot appears that indeed in case SVR performs well at lower AQI levels, the restrain of blunder develops as the genuine AQI values rise. Maybe since these are more complicated extraordinary illustrations, the show performs ineffectively when contamination levels rise, as prove by this extending spread. The fractional victory of the demonstrate in bookkeeping for AQI change is shown by the Worldwide R2 esteem of 0.45.

4.2.Random Forest Regression (RFR)

Arbitrary Timberland Relapse (RF) is a fake insights outfit procedure that makes a set of choice trees for persistent variable expectation. By amassing the forecasts of person trees, RF diminishes relationship between person expectations and, subsequently, generally mistake. RF works particularly well with expansive highlight spaces and is especially viable on enormous information. Two principal parameters that altogether affect a Irregular Woodland model's capacity to foresee are the measure of the arbitrarily chosen factors and the outfit estimate of trees. Tried at each division, Irregular Woodland essentially decreases the chance of overfitting by combining the forecasts made by numerous trees, coming about in a more precise generalization. The technique guarantees that the ultimate estimate could be a great agreement by utilizing the advantages of a bunch of choice trees. In this sense, Irregular Woodland Relapse could be a dependable and flexible approach for the larger part of information science relapse errands. The Arbitrary Timberland Regressor (RFR) was chosen for this consider since to its tall viability in processing large sums of information with numerous highlights, which makes it perfect for AQI forecast. An R2 esteem of 0.95, which takes into consideration the instability in AQI comes about, appears that RFR performed discernibly superior than SVR, whereas being instructed and tried essentially.Usually due to RFR's gathering learning approach, which employments numerous choice trees to avoid overfitting and reinforce the model's generalization over different information illustrations.

4.3.XGBoosting

Extraordinary Angle Boosting, or XG Boost, could be a effective machine learning procedure that exceeds expectations at relapse and classification. In arrange to move forward anticipated exactness, it builds on a slope increasing worldview, in which each ensuing show endeavors to rectify the botches of the past ones. This method's capacity to appropriately handle lost information is one of its fundamental focal points, which makes it suitable for real-world applications where datasets are as often as possible deficient. Regularization techniques are moreover joined into XGBoost to anticipate overfitting and improve the model's capacity to generalize viably to new, untested information. In comparison to customary strategies, the calculation is outlined to bolster parallel handling, which incredibly quickens the preparing prepare.With its broad hyperparameter tuning settings, clients can maximize the execution of dataset-specific models. Since of its viability and effectiveness in prescient modeling, XGBoost has been broadly utilized in a assortment of disciplines, such as natural checking, wellbeing, and fund. Since of its amazing prescient control and greatly quick computation speed, particularly for unthinkable data, XGBoost was chosen. Since XG Boost may be a angle boosting procedure, it develops choice trees successively, attempting to settle the mistakes of its forerunners. The AQI's expectation precision is altogether moved forward by this iterative strategy. With a surprising R2 score of 97%, the demonstrate was able to clarify 97.04% of the change in AQI values.Performance measurements on test, preparing, and approval sets were assessed, affirming XG Boost's predominant viability over competing models.

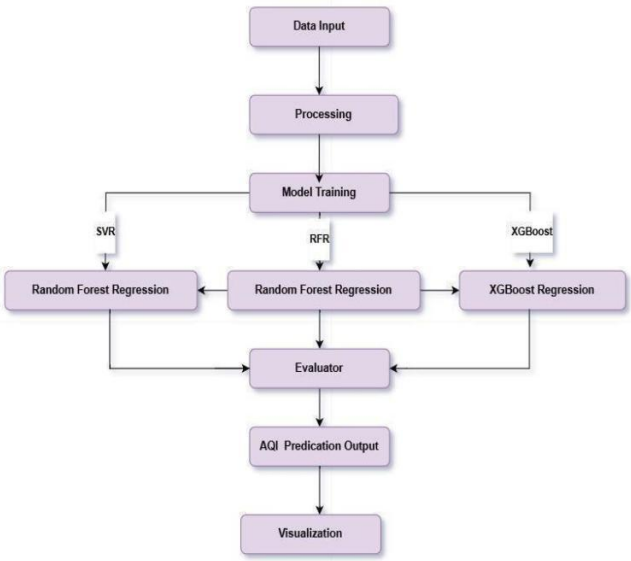

Fig 1.1 Architecture of the proposed model

5

.Mathematical Equations

Mathematical Formulas for Air Quality Prediction Using Machine Learning Models Machine learning models are used in air quality prediction to capture the interactions between different contaminants and atmospheric variables. Here are the basic formulas used in AQI computation and machine learning AQI prediction models, including XGBoost Regression, Random Forest Regression, and Support Vector Regression (SVR).

Calculation of Air Quality Index (AQI)

The Air Quality Index (AQI) is a standard scale that translates pollutant concentrations to a single number, indicating the level of severity of air pollution. The AQI for a particular pollutant can be calculated as follows:

$$AQI_p = \frac{I_{high} - I_{low}}{BP_{high} - BP_{low}}(C - C_{low}) + I_{low} \quad \text{----------(1)}$$

AQI_p - *AQI* for pollutant p

C - actualconcentration of the pollutant

I_{High}, I_{Low} / BP_{high}, BP_{low} -breakpoints of pollutant concentration/corresponding AQI values

5.1.Support Vector Regression (SVR) for AQI Prediction

Support Vector Regression (SVR) estimates AQI values by finding a function that best fits the input data while minimizing errors within a margin ε

$$f(x) = w^T \phi(x) + b \text{-------(2)}$$

w - weight vector

$\phi(x)$ - kernel function mapping inputs to a higher dimension

b - bias term

SVR minimizes the loss function:

$$\frac{1}{2}||w|| + C\sum_{i=1}^{n} \max(0, |y_i - f(x_i)| - \varepsilon \text{ ----------} \quad (3)$$

5. 2. Random Forest Regression (RFR) for AQI Prediction

Multiple decision trees are used in Random Forest Regression (RFR), an ensemble learning technique, to improve accuracy. The outputs from each individual tree are averaged to provide the expected AQI.

$$\hat{h}(x) = \frac{1}{T}\sum_{t=1}^{T} h_t(x) \quad \text{----------(4)}$$

T - total number of decisions tree

$h(x)$ - AQI prediction from tree (t)

5.3. XGBoost Regression for AQI Prediction

To maximize prediction accuracy, XGBoost (Extreme Gradient Boosting) constructs decision trees in a sequential manner. The AQI prediction function that has been updated is:

$$(\text{푦̂}) = \text{푦̂}_{\text{푡}-1}(\text{푦̂}) + \text{훼}h_{\text{푡}}(\text{푦̂}) \text{---(5)}$$

(푦̂) - at iteration

$\text{푦̂}_{\text{푡}-1}(\text{푦̂})$ - previous model

$h(\text{푦̂})$ - new decision tree adjusting previous errors

The loss function combines prediction errors and modelcomplexity

$$L = \sum_{\text{푖}=1}^{\text{푛}} l(\text{푦}_{\text{푖}}, \text{푦̂}_{\text{푖}}) + \sum_{\text{푡}=1}^{\text{푇}} \Omega(\text{푓}_{\text{푡}}) \text{ ---------- (6)}$$

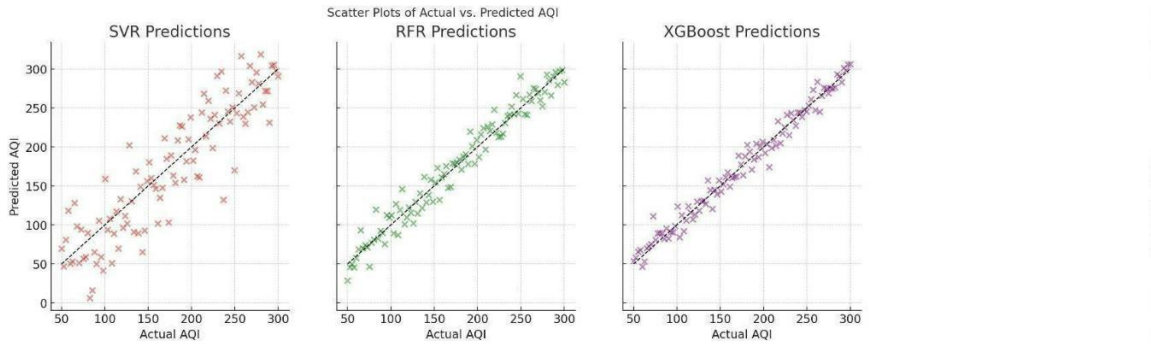

Fig 1.2 SVR Predictions , RFR Predictions, XGBoost Predictions

6.Metrics for Model Evaluation

A variety of statistical measures have been used to evaluate how well machine learning models predict AQI.

6.1.Coefficient of Determination (R^2 Score):

The model's ability to explain the variance in AQI values is determined by the R square.

$$\text{푅}^2 = 1 - \frac{\sum(y_i - \bar{y})}{\sum(x_i - \bar{x})} \text{ ----------(7)}$$

6.2.Mean Absolute Error (MAE):

The average absolute difference between the actual and predicted AQI values is calculated by MAE.

$$\text{MAE} = \frac{1}{n}\sum_{i=1}^{n} |y_i - \hat{y}_i|$$

where n is the total number ofobservations.

6.3.Root Mean Square Error (RMSE):

By penalizing larger errors, RMSE quantifies prediction errors:

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n} (y_i - \hat{y}_i)^2}$$

Better modelperformance can be observed by lower RMSE values.

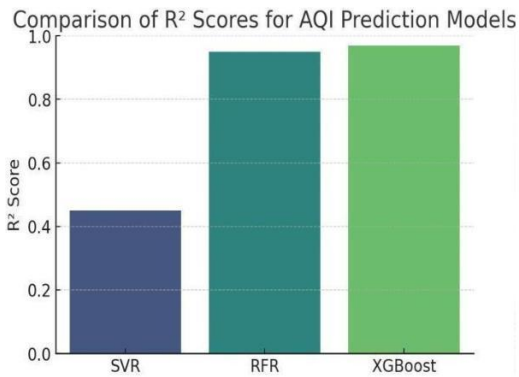

Fig 1.3 comparison of R square for AQI Predictions Models

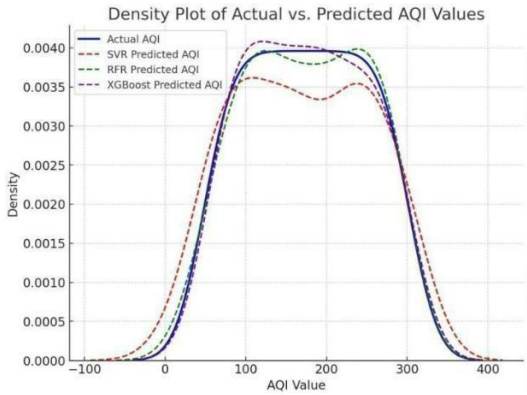

Fig 1.4 Density Plot of Actual vs Predicted AQI values

7.Results and Discussion

Introductory assessments of the models uncovered critical varieties in their exhibitions, especially in terms of mistake measures such as Cruel Supreme Blunder (MAE), Cruel Squared Mistake (MSE), and Root Cruel Squared Blunder (RMSE). The Bolster Vector Relapse (SVR) show recorded the most noteworthy blunder rate. As anticipated, confirming its destitute execution in estimating AQI. SVR recorded a moo R^2 esteem of 45%, demonstrating its destitute capacity to clarify the alter in AQI values. This brought the journey for more complex models to extend prescient precision. Irregular Timberland Relapse (RFR) and XG Boost fitted into this case here. Blunder measurements were much diminished by both models, which demonstrated to be remote predominant. With an R2 of 97.2%, XG Boost outflanked the Irregular Timberland show, which had an R2 of 95.7%, showing more prominent prescient potential. Moreover, XG Boost demonstrated viable on its claim at bringing down botches in expectation since it created lower MAE and RMSE than other models.

Metrics	SVR	RFR	XGBoost
MAE	10.213	0.896	1.058
RMSE	16.808	4.694	3.803
R square	0.453	0.957	3.803

Table 1.2

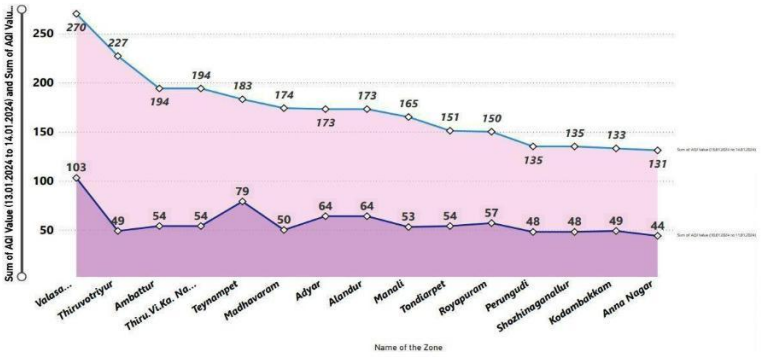

Fig 1.5 Graphs for AQI values

8.Conclusion

This think about highlights the noteworthiness of prescient machine learning models like irregular woodland bolster vector machines and XGBoost in foreseeing PM2.5 and PM10 levels. The models are more precise and reliable than conventional forecast strategies, giving superior discuss quality gauges. The quick industrialization and urbanization of creating countries has contributed essentially to the rise in discuss contamination levels, especially in urban cities like Chennai, India. In expansion to highlighting the need for localized optimization, the comparative investigation of different models over a few cities appears contrasts in effectiveness. The affectability investigation too recognizes the foremost imperative components impacting particulate matter levels, helping natural offices and policymakers in executing focused on Methods for lessening contamination These determining models can be valuable assets for early caution frameworks that permit for preventative activities to decrease discuss contamination and safeguard human wellbeing within the future. Determining and controlling discuss quality may be assist moved forward by coordination genuine- time information sources and expanding demonstrate exactness utilizing cutting-edge profound learning calculations. To diminish the negative impacts of discuss contamination on the environment and human wellbeing, green city arranging and stricter outflows controls are still required.

Abstract - Electronic Waste Management which is also called as E-Waste is the collection of discarded and damaged electronic devices such as ICT devices etc. It is managed because it contains hazardous and harmful materials like lead , mercury , cadmium , as well as gold, silver , copper , and rare earth metals . Our aim in this paper is to create a mobile app that connects users , service personnel and workshops , calculate payments based on e-waste quantity and optimizes routes for service personnel. It reduces travel time , increased user participation which improved efficiency for workshop and service personnel**.**

Keywords - E-waste management, mobile application, user interface, recycling workshops, service optimization, payment system.

INTRODUCTION

E-Waste is abbreviated as Electronic Waste. When E-Waste are clustered among a particular area it is complex to handle due to its harmful substances that have an adverse impact on human health and environment . There is a need for proper technology to handling , dispose and recycling of these chemicals. Basel Convention characterizes E-Waste as hazardous when they contain and are contaminated with mercury, lead, cadmium, etc. Wastes containing insulation or metal cables coated with plastics contaminated with or containing lead, coal tar, cadmium, etc are also characterized as hazardous wastes.

E-Waste is either buried in landfills or informally recycled in developing countries exposing workers to hazardous substances but also harmful substances like lead or brominated flames retardants.

Unsafe disposal practices and environmental damage are common issue , leading to e-waste toxic nature. Lack of transparency in e-waste collection and recycling discourages people from using it. An efficient system is needed to collect and ensure transparency in e-waste collection and recycling.The smart e-waste management system is the digital platform that streamlines e-waste collection and disposal . Users submit collection requests and images, and the system assigns the nearest centre by shortest distance . A Service Person inspects and reports the waste, based on the report the system predicts the price for the item using custom datasets. Cancelling non-recyclable requests if necessary. The system promotes responsible e-waste disposal reduce environmental impact increases transparency and minimizes it proper accumulation.

HAZARDOUS COMPONENTS AND ITS EFFECTS

S.No	Components	Effects
1	Arsenic	Arsenic may cause Bladder Cancer.
2	Barium	It is dangerous due to its toxic compounds and can disrupts heart rhythm and blood pressure.
3	Beryllium	It is also known as Human Carcinogen , often referred to be associated with lung cancer.
4	Hexavalent Chromium	Chromium affects Liver, Kidney and Resipratory System.
5	Cadmium	It cause damage to the quality of Soil and Water.
6	Mercury	Mercury leads to pollute the Environment through various resources and potentially affects human and animal health.
7	Lead	Lead causes Anemia, Kidney Damage and reproductive issues.

Table No:1 Hazardous Components And Its Effects

SOURCES OF E-WASTE

Office Equipment

This includes discarded photo copiers , scanner , printers , fax machines , and other electronic device used in office environment.

Appliances and White Goods

E-Waste is also generated by appliances such as refrigerated , washing machines , dryers , and other household electrical equipment etc.

Medical Device

Equipment used in healthcare facilities , such as X-rays machine , MRI machines , Ultrasound devices , Medical monitors , and Laboratory equipment , and become ewaste when they are no longer in use.

Miscellaneous Electronic Devices

Electronic Devices such as Smart Watches, Laptops ,and various other Electronic gadgets on all sizes .

LITERARTURE REVIEW

Ram Krishna, DDG(FA), New Delhi,[1] The Study Concludes that the ITU has agreed to the fact that there is no any unique model in the today's technological world for E-Waste Management System.

Rahul S Mor, Kuldip singh Sangwan ,et.al, [2] The Paper tells about how E-Waste is harmful to human health and Environment as it releases so many hazardous and toxic substances like arsenic, beryllium and barium etc,which can affect Human Health and Environment Sustainability.

Deepak Adhana,[7] The paper talks about the Global Scenario of E-Waste Segregated and also the paper ends with the study of State Wise and City Wise E-Waste collected along with their Recycling Formalities and the impact of Human Health and Environment.

Minh-Hieu Le , Jui-Chen Chang,et.al,[9] The primary Objective of this paper is to improve the Recycling Method to enhance the Quantitative Analysis Techniques to Collect the E-Waste.

FLOW CHART

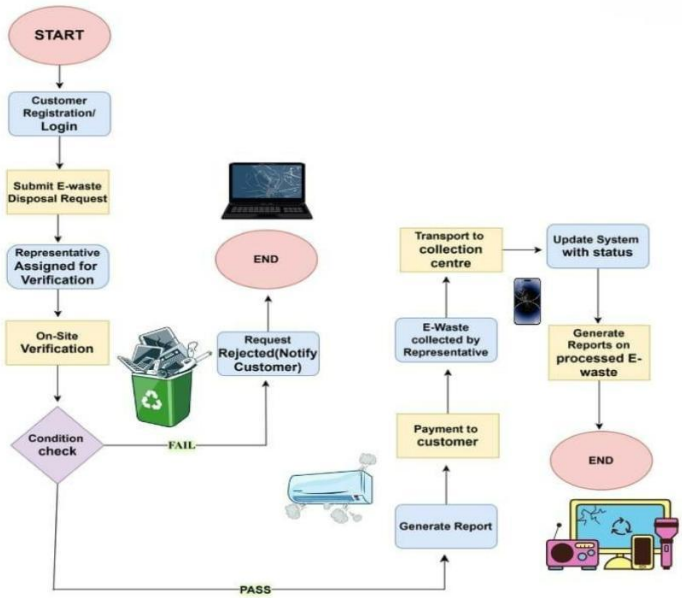

Fig.1: User Site

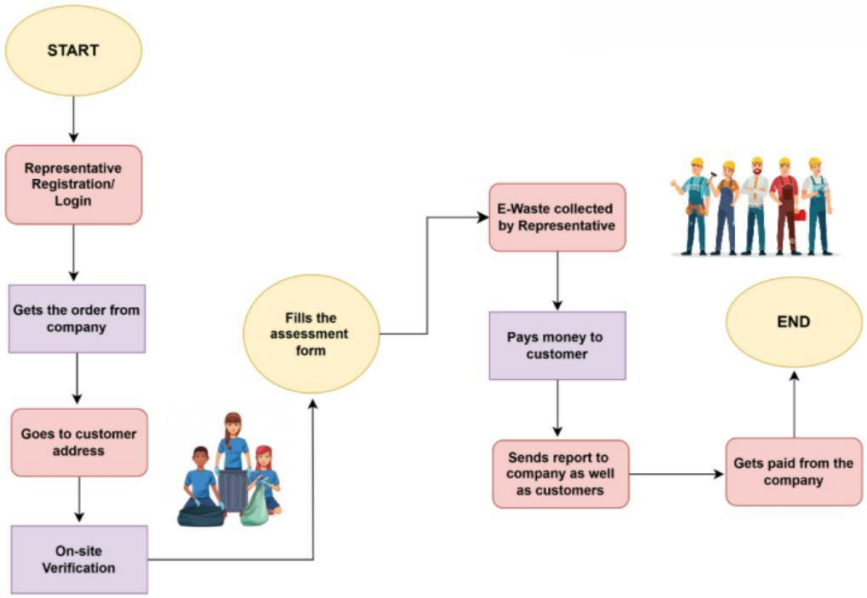

Fig.2: Service Site

Fig.3: Company Site

METHODOLOGY:

User Site

The process begins with the customer registering or logging into the online platform, where they can access e-waste disposal services. After logging in, the customer submits a disposal request by providing essential details such as the type of e-waste, its quantity, brand , year of manufacture and the pickup location of the customer. Once the request is submitted, the company assigns a representative who is near by the customer location to handle the task. The representative's first responsibility is to visit the customer's location to conduct an on-site verification and condition check based on the disposal request submitted by customer. This step is crucial or important role to ensure that the e-waste meets the company's criteria for disposal or recycling.

There are two possible outcomes at this stage that is the representative should check two condition either pass or fail . If the condition check fails—meaning the e-waste does not meet the required standards for the recycling. the representative reject request of that customer and me report to the company, and the process ends. However, if the condition check passes, the representative moves forward with the next steps. They generate a detailed report documenting the condition, type, and quantity of the e-waste. If the company's policy allows, the representative pays the customer for the e-waste based on predefined rates, this payment is calculated by using predefined rates .This predefined rates are trained by the famous algorithm called random forest ,which may depend on factors like weight, type, brand, and market value.

After payment, the representative collects the e-waste and arranges for its transportation to the company's designated collection center .The representative get insight for his perform from the company. Throughout this process, the representative update status of the request in real-time, ensuring transparency and faith for both the company and the customer. Once the e-waste arrives at the collection center the company start the process of recycling and the final report is generated, summarizing the entire process, including verification, collection, payment, and transportation details in the online platform and also this report is shared with the company for internal records and with the customer for their reference. The e-waste is then processed or recycled in proper precaution which is environmentally responsible manner. This streamlined process guarantees efficiency, accountability, transparency and customer satisfaction while promoting sustainable e-waste management practices in day to-day life. The representative serves as a vital bridge between the customer and the company, ensuring that every step is executed consistently and every step is executed without compromising compliance or adjustment with the company's terms and condition.

Service Site

The process starts with the representative registering or logging into the company's platform, where they gain access to their assigned tasks and orders. Once an order is received, the representative reviews the details of the gadgets, including the customer's address by referring longitude and latitude mention by them during the registration and then the he collect the e-waste from the user . They then proceed to the customer's location, where they perform an on-site verification to confirm that the e-waste matches the description provided in the order. This step ensures accuracy and prevents discordance. After verification, the representative fills out a detailed assessment form in front of customer for increasing the transparency , recording specifics such as the quantity, condition, type , brand and category of the e-waste, which is crucial for proper recycling or disposal.

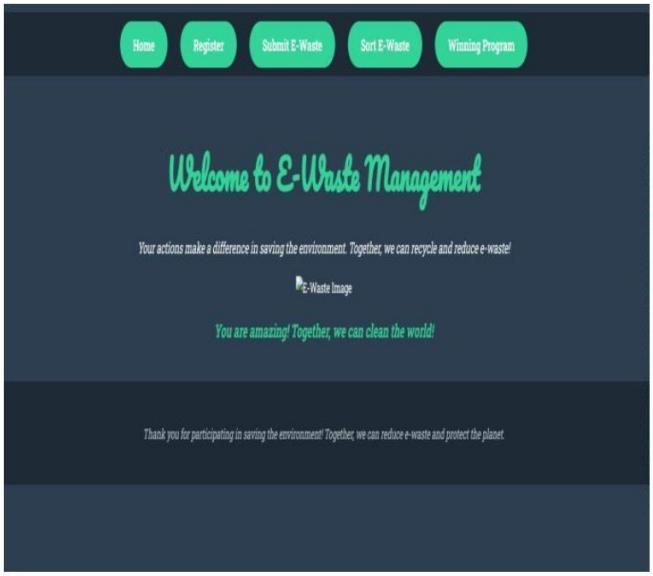
Once the assessment is complete, the representative collects the e-waste from the customer for the recycling process. Depending on the e-waste, the representative will compensate the customer on the spot, either based on the weight, type, or value of the e-waste and quantity. This payment is calculated by using predefined rates .This predefined rates are trained by the famous algorithm called random

forest. After the collection and payment process, the representative prepares a comprehensive report, which includes the assessment form, payment details, and any other relevant information. This report is submitted to the company for processing and is also shared with the customer for transparency and record-keeping purposes.

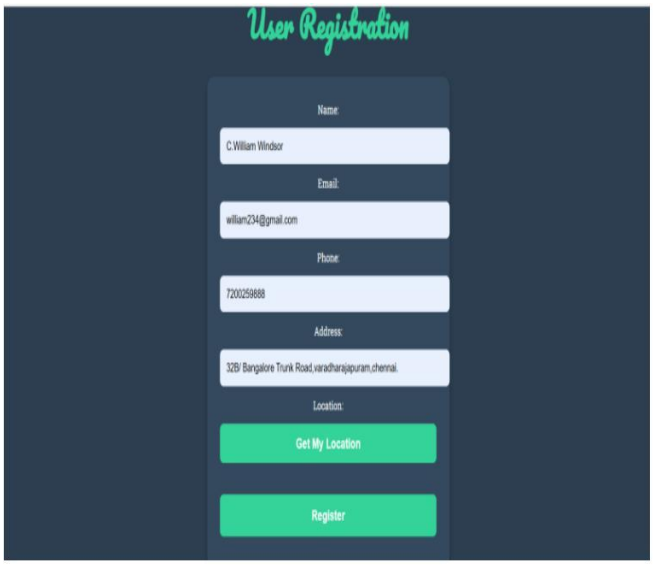
The company then reviews the report, processes the e-waste, and compensates the representative for their services. This entire workflow ensures a seamless and efficient e-waste collection process, emphasizing accountability, environmental responsibility, and customer satisfaction. The representative acts as a critical link between the company and the customer, ensuring that all steps are followed strictly, from verification and collection to documentation and payment. This process not only promotes recycling and sustainability but also builds trust and reliability in the e-waste management system .And this representative play a major roll between the user and company.

Company Site

Users can sign up or log in to the system's home page. Users are taken to the Dashboard after logging in, which acts as the main location for checking important performance statistics and accessing different modules.



An overview of key indicators, including Total Revenue per Month and Requests per Day, is given by the Dashboard, which gives information on the system's operational and financial performance. In order to ensure efficient communication and problem solving, users can access the client Queries section and manage and reply to client inquiries. Users can also access and manage worker information by classifying workers as Active or Inactive according to their current engagement status using the Worker Details module.The worker tracking is one of the important features in the system. it's enabling the users to monitor the activities of the worker. Pending requests, or assignments that have been assigned but not yet done, and completed requests, or tasks that have been successfully performed, are both tracked in this way. This module guarantees efficient monitoring and management of task progress and employee productivity.



Through the integration of financial data, employee activity tracking, customer interaction management, and user identification onto a single platform, the system is intended to optimize operations. New users can register and use the system with the Signup feature, while returning users can access it securely with the Login option. The Dashboard act as the main interface, it is a overview of the system's functionality and making it simple to access the other modules. And the system is mainly designed to improve the productivity ,handling the client queries and financial data

CONCLUSION

Electronic devices is gaining its popularity in the world of Nature, due to this setting the E-Waste gets simultaneously increased so unsafe disposal practices is a common issue, leading to toxic nature and it takes more time to destroy the waste. This paper aim is to manage the waste and improve the efficiency through the mobile app. our project serves as a transformative bridge between users, e-waste workshops, and service personnel. it revolutionizing the way e-waste is collected and processed. By using technology, to reduce the travel time for service personnel, ensuring efficient and timely to collect the e-waste from the users. Our innovative software not only calculating the payments based on the quantity of e-waste but also enhances user convenience by identifying nearby workshops. This approach is benefits for all stakeholders: users receive fair compensation and a hassle-free experience, workshops gain increased access to e-waste materials, and service personnel enjoy improved efficiency and get credits for their efforts. It is a worthy, admirable and economical solution for E-Waste surveillance and recycling. This paper concludes to the idea to create a model to reduce the efficient time and travelling distance on collecting E-Waste to avoid harmful substances in order to safeguard the habitat. And the sustainable ecosystem that promotes environmental responsibility, economic incentives, and paving the way for a greener and more connected future**.**

ABSTRACT: *The integration of quantum computing and machine learning has given rise to a transformative approach in drug discovery, enabling faster, more accurate, and cost effective solutions. Drug discovery traditionally relies on computational methods to simulate molecular interactions, optimize drug candidates, and predict biological effects, a process that is often computationally intensive and time-consuming. Quantum machine learning (QML) leverages the unique properties of quantum computing, such as superposition and entanglement, to process complex datasets and perform calculations that are intractable for classical systems. This synergy enhances molecular simulations, offering greater precision in predicting protein folding, molecular interactions, and drug receptor binding affinities. Furthermore, QML-based optimization algorithms can accelerate the identification of potential drug candidates by exploring vast chemical spaces more efficiently than classical methods*

III. QML FOR DRUG DISCOVERY

3.1 Approaches

We present a half breed generator and classic discriminator quantum GAN that's qubit-effective and dependable for learning nuclear structures successfully within the soul of the classic MolGAN design. Execution of the fathomed circuit configuration is observed by mapping it to the initial single overwhelming generator circuit by approximations just like the Fréchet remove and drug-like property scores. Quantum GAN half breed generator (QGAN-HG) comprises of parameterized quantum circuit to create highlight vector with qubit assess estimation and classical key neural organize giving basic molecule vector and bond framework for molecule representation on the chart. In expansion to this, a novel

variation has also been proposed, the parameterized Quantum GAN with half breed generator (P-QGAN-HG), that varies from QGAN-HG because it includes a quantum circuit composed of interfacing a subset of quantum sub-circuits. The variational quantum circuit comprises three endlessly fundamental steps.initialization, trap, and estimation. The default half breed generator organize can be a common neural organize with an input layer enduring the consolidate vector of pined for values. Shockingly, 85.07% and 98.03% of the generator parameters are tuned absent from the default GAN, demonstrating the solid expressiveness of the quantum circuits. We too accomplish two modern tunings of QGAN-HG with L = 2 and N = 10 parameters. Experimentation is done on the QM9 dataset. Atomic transport created is gotten by building a dataset of particles wherein genuine particles are arbitrarily chosen from the same number of molecules in QM9. Estimations such as drug-likeness, dissolvability, and synthesizability with RDKit test the rightness of arranged sedate. The learning rate is 0.0001 and the ruin rate is 1/2000 each 3000 eras. Until arranging will be arranged for 5000 ages with early ceasing concurring to the Fréchet separated. An outline of a comparison between MolGAN and QGAN-HG running with L = 2 and N = 10 is given underneath.

3.2 Dataset

The data set employed in this case is 4095 tests all from a tensor of estimations of size 14x32x32x32 having 14 channels the data set includes 1553 nucleotide-binding pockets 596 heme-binding pockets and 1946 other protein sort pockets a channel of the data set is deleted as the protein cache for testing

Algorithm	ACC	PPV	TPR	TNR	AUC
DeepDrug3D	0.956	0.815	0.909	0.964	0.987

Agri Sense: Pre-emptive Disease Detection and Forecasting Platform

Abstract—Crop diseases can severely affect farmers' livelihoods, especially in regions where certain crops are more vulnerable to specific diseases. To help farmers tackle this challenge, we developed a web-based application that uses cutting-edge deep learning technology to predict crop diseases early and accurately. For crops like beans, citrus, rice, and tomatoes, users can simply upload images of their crops, and the system analyzes them using Convolutional Neural Networks (CNNs) to detect any signs of disease. The models were built using TensorFlow and Keras, with techniques like data augmentation to make the system more reliable. Additionally, the application offers a disease forecasting feature where farmers can input information like temperature, humidity, and crop type to assess the risk of disease in advance. Upon detecting any disease, the system provides personalized treatment recommendations and makes it easy for farmers to purchase the necessary products through an integrated e-commerce platform.

Key words: Image-based diagnosis, TensorFlow, Keras, ImageDataGenerator, environmental data, disease forecasting.

I. INTRODUCTION

In agriculture, crop disease is one of the primary factors limiting productivity and results in significant losses and costs to the farmer, particularly for commodities such as tomatoes, rice, beans, and citrus, which suffer billions of dollars in annual losses. With a growing global population, early illness identification is critical to food security.Currently, illness detection is based on visual inspections, which can be time consuming and subjective. Many diseases are asymptomatic

until major damage occurs, resulting in delays in diagnosis and treatment.Advances in deep learning and image processing open up new avenues for automated disease diagnosis utilizing Convolutional Neural Networks. However, present systems frequently lack integration with climate data, resulting in mistakes and insufficient treatment recommendations. To address these concerns, we created a web-based application that integrates image-based disease detection, environmental forecasting, and treatment recommendations. Key benefits of our system include timely detection, actionable insights, and e-commerce integration, enabling farmers to respond quickly to outbreaks, reduce crop losses, and easily acquire necessary treatments.

II. LITERATURE SURVEY

To strengthen the detection algorithms, Nagababu et al. designed a full structure for the diagnosis and detection of plant diseases. Such framework presents a number of techniques. Saeed et al. applied Convolutional Neural Networks to develop a multi-crop disease detection and classification technique which brought out the prowess of deep learning in disease identification across varying crop types. In the quest to develop a system for the detection of plant diseases with subsequent cropping recommendations, Kumar at al. adopted CNN. and machine learning approaches, which successfully addressed both diagnosis and treatment alternatives [3] Bag and his coworkers further contributed to the growing area of research on the use of advanced algorithms in agriculture by investigating crop leaf disease detection in soybean crops through deep learning techniques [4]. According to Jha et al., in order to improve various aspects of agriculture, accurate classification systems are essential, which is why a classifier methodology using deep learning for crop disease detection and classification was developed [5].The necessity for comprehensive solutions was highlighted by Suram et al. when they created an integrated crop disease detection system that offers farmers corrective measures [6].By using a CNN-based strategy, Kumar et al. improved crop health management precision for papayas, highlighting the potential for early disease diagnosis in particular crops [7]. In their research focused on the use of deep learning models for the diagnosis of crop diseases, Haider et al. showcased a number of techniques and their effectiveness [8]. Ai et al. investigated deep learning-based recognition models for agricultural illnesses and insect pests, especially in challenging conditions, demonstrating the resilience of these models [9]. In their research conducted by Tussupov et al., use of formal verification proved to be beneficial in agricultural practices particularly in the study of machine learning approaches to crop disease pest verification [10]. Focusing on species that attack horticultural crops and agricultural crops, Pujari et al. attempted to improve diagnosis of plant diseases by studying

image processing techniques in identifying and classifying fungal infections [11]. To illustrate the application of technology ambitiously, Islam et al. introduced “DeepCrop”, an online web-based tool that employs numerous deep learning algorithms to authoritarian agricultural diseases. It was also Nandhini and Ashokkumar who stressed the importance of image-based methods in crop disease prediction through leaf images analysis using machine learning techniques [13]. Addressing the prediction accuracy, Pokkuluri et al. designed a cellular automata - augmented convolutional neural network (CNN) based crop disease forecasting model [14]. To conclude this paper, works undertaken in the area of crop disease prediction employing artificial intelligence and especially machine learning are presented in a broad review by Patil and Manohar [15].

III. PROPOSED SYSTEM

Crop diseases are serious risks to modern agriculture, resulting in large financial losses and food shortages, especially in places with sensitive crops. Traditional disease identification is based on manual scanning by farmers or agronomists, which is time-consuming, subjective, and depends on the inspector's experience. This might result in undiscovered or misdiagnosed diseases,causing crop loss and reducing overall agricultural productivity.Current automated detection techniques frequently fail to incorporate important environmental variables like temperature, humidity, rainfall, and soil pH, rendering disease forecasts incorrect. Ignoring these elements leads to erroneous forecasts and untimely breakouts. Furthermore, many present options lack clear treatment recommendations, leaving farmers with no advice for controlling recognized diseases.An integrated system that integrates advanced image processing technologies with environmental data is required to improve illness diagnostic accuracy. This would allow farmers to respond to outbreaks more quickly and deploy tailored treatments, ultimately boosting crop health and preserving food security in the face of increasing agricultural problems.

A. System Architecture

The first stage involves acquisition of data where both healthy and diseased plants are photographed for storage purposes.This data is then pre-processed, which involves rescaling and resizing the images to ensure consistency. The data that has gone through a series of processes is then inserted into a convolutional neural network (CNN) which is a variant of an artificial neural network particularly used for image recognition. It is the anatomy of the images that are examined by the CNN in order to determine the health status of the plant. However, After completion of training of the CNN, it is then possible to determine the health status of the plants based on the images of clean plants.

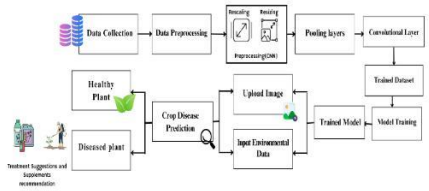

Fig 3.1 Architecture Diagram

Data Collection:

The process starts by gathering data from various sources. This could involve an accumulation of pictures of healthy crops and those affected by diseases alongside environmental aspects such as types of soil, weather, and previous crops grown.

Preprocessing of Data:

The gathered data will undergo preprocessing for the training of the machine learning model. This will include resizing, rescaling, and normalization of the images.

Crop Disease Prediction:

The provided pre-processed data is inputted into deep learning algorithms probably Convolutional Neural Networks to associate the patterns with the disease and train them. The model provides a prediction for the disease most likely to affect the crop.

Input Environmental Data:

In addition, the system enables the input of climatic factors. This will be beneficial in disease forecasting. For instance, understanding the moisture content in the soil as well as the duration of the last rainfall, will assist in diagnosing the environment conducive to a particular disease causing organism.

Treatment Suggestions:

The system may give recommendations on the proper treatments and supplements which should be

applied according to the expected disease. For example, advices of types of pesticides, fungicides or fertilizers that should be applied, cultural practices that may help in controlling further disease spread, etc.

This system targets to be utilized by farmers, agricultural professionals, and researchers in management crop health and in reducing crop losses due to diseases.

Here are some key features and benefits of the system:

- **Early Detection**
- **Targeted Treatments**
- **Lower Crop Losses**
- **Sustainable Practices**
- **Accessible Information**

B. Dataset Description:

The section outlining the characteristics of each module data set, gives an overview of the various data attributes that were used for training, testing or evaluation of the machine learning models. Such expositions are crucial in assessing the performance of the models and in recognizing potential improvements.

The common attributes in the modules emphasize the similarity in the approach used for the development and training of the models. Such similar attributes can be used to develop a more widely applicable framework for predicting plant diseases.

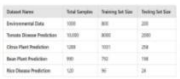

Fig 3.2 Dataset Description.

C. Algorithms

Convolutional Neural Networks (CNNs): The Visionary Force Behind Image Recognition

Exploring the Architecture of CNNs:

Essentially, the architecture of a CNN is based on emulating the visual system of humans. While the traditional convolutional neural networks approach images as flat arrays of pixels, CNNs take them apart by a series of specialized layers that progressively extract meaningful features. This stratified approach helps CNNs to learn the complexity of patterns and spatial relationships present in the image data.

The Building Blocks of a CNN:

Convolutional Layers: As convolutional layers make small use of certain filters which are referred to as kernels which cover a certain region of the input image in order to extract image features. Each and every filter is meant to extract a different feature, like edges or texture, and goes over the underlying pixels to compute the dot product and generate a feature map.

Formula: **Output = (Input * Filter) + Bias**

Pooling Layers: These layers reduce dimensionality by summarizing information within small regions of the

feature map, typically by taking the maximum or average value.

Formula**: Output = max(Input) (for Max Pooling)**

Fully Connected Layers: These layers learn complex relationships between features, enabling the network to make predictions.

Formula: **Output** = **softmax(W * Input + Bias)**

D. Random Forest Classifier:

The Random Forest Classifier is an ensemble learning approach that combines the results of multiple decision trees to improve the accuracy and reliability of predictive results.

Data Preparation:

1. Information Gathering: Compile datasets that include appropriate labels. Fig. 3.3 Illustrates the significance of each feature within the Input Environmental Module.

2. Data Preparation: Ensure the raw dataset is clean and ready for use by fixing incomplete data, adjusting ranges, and transforming non-numeric variables into numerical form

.Model Training:

1.Forest Construction: Generate several decision trees where each learner is trained based on a random fraction of the data and fractional set of features..

2.Tree Growth: Grow each decision tree to its full depth without pruning, allowing it to capture intricate patterns in the data.

Decision Tree Formula:

Prediction = argmax ∑ (Feature * Weight) + Bias

- Feature is the input feature
- Weight is the learned weight for each feature
- Bias is the learned bias term

Random Forest Formula:

Prediction = ∑ (Tree_Prediction * Weight) / ∑ Weight

- In general, the weight given to trees, which is usually 1/n where n = number of trees is known as the weight of any tree.
- Tree_Prediction refers to the outcome produced by each separate decision tree.

Model Evaluation:

1.Out-of-Bag Error: Out-of-bag data helps in assessing model's performance on the data not used in the training of each tree.

2. Hyper Parameter Optimization: The performance of the model can be improved by varying the hyperparameters of the model such as number of trees, number of features considered at every node, number of leaves in a tree among others.

Model Deployment and Prediction:

1.Prediction: Make predictions using the trained Random Forest model by averaging the predictions from all trees (for regression) or taking the most common class (for classification).

Prediction Formula:

For regression:

Prediction = ∑ (Tree_Prediction) / n

- Tree_Prediction refers to the forecast made by a single decision tree.
- n denotes the number of trees

For classification:

Prediction = argmax ∑ (Tree_Prediction == Class)

- Class - the predicted class label

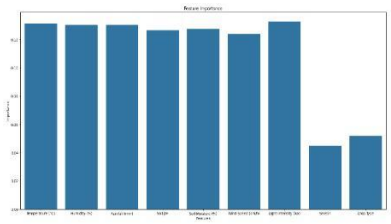

Fig 3.3 Feature Importance

E. Confusion Matrix

Each crop disease prediction module has confusion matrices that provide this kind of insight into such performance.

The Input Environmental Data Module verystrongly predicted conditions leading to the disease. All 135 instances were classified correctly into class 3; however, the model was able to predict one instance of class 0 (Blight). Misclassifications took place mostly within classes 1 and 2. Fig 5.4 Shows Confusion Matrix for Environmental Data Module

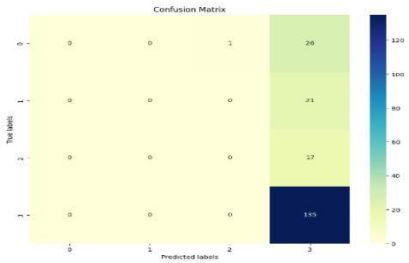

Fig 3.4 Confusion Matrix for Environmental Data Module

Within the context of the Module Rice Plant Disease Prediction, the main focus was on the accurate detection of Bacterial Leaf Blight, Leaf Brown Spot and Leaf Smut, in a more detailed and diagnostic matrix with lighter diagonal cells accurately representing the boundaries of the diseases. There were also instances of confusion between the classifications of the Brown Spot and the Leaf Smut suggesting that further work needs to be done towards the clear separation of those two diseases.

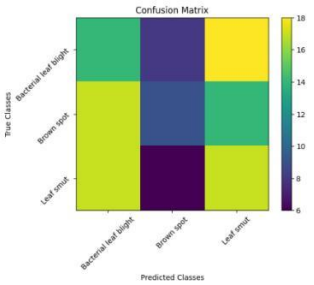

Fig 3.5 Confusion Matrix for Rice Disease Prediction Module

The Bean Disease Predictor was able to accurately identify Bean Rust and Healthy plants but could not with Angular Leaf Spot because there are darker diagonal cells and many instances of it have been incorrectly identified as Bean Rust. This goes to show that while the model is fairly strong overall, its performance in the cases of Angular Leaf Spot is still rather disappointing.

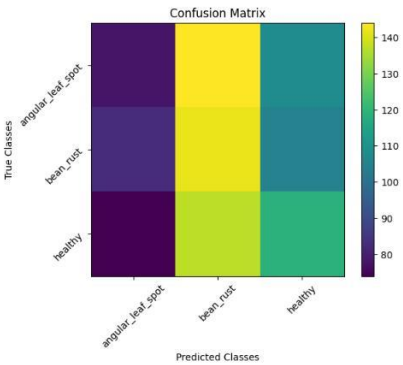

Fig 3.6 Confusion Matrix for Bean Plant Disease Prediction Module

The Tomato Plant Disease Prediction Module, though successful in predicting various diseases present, included some diseases such as Early Blight. It was observed that notable misclassifications occurred between Septoria Leaf Spot and Spider Mites.

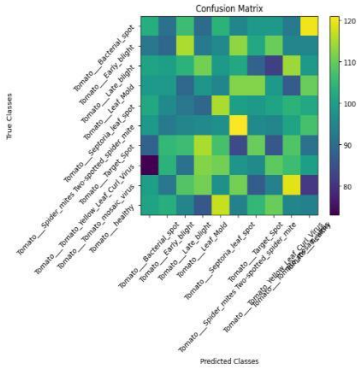

Fig 3.7 Confusion Matrix for Tomato Plant Disease Prediction Module

Most importantly, Citrus Disease Prediction performed very well in correctly identifying citrus-canker because of high correct prediction counts in the confusion matrix. It, however underperformed with moderate misclassification rates for black-spot detection. In general, this module showed solid performance but also notified that it requires improvement on the black-spot detection capability.

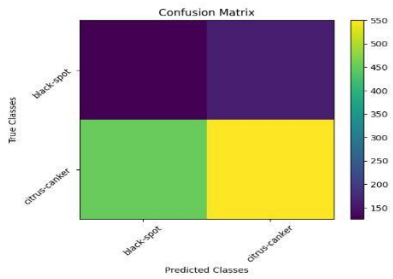

Fig 3.8 Confusion Matrix for Citrus Plant Disease Prediction Module

E. Technical Stack

Hardware Requirements:

- Processor: Intel Core i5
- RAM: 512 MB and above
- Hard Disk: 40 GB and above

Software Requirements:

- Programming Language: Python
- Technology: DeepLearning,Machine Learning
- Operating System: Windows 11

Libraries:

- NumPy: Essential for numerical computations and efficient data manipulation.
- • TensorFlow: A library for designing and running machine-learning models, particularly those which involve large datasets or are otherwise complex.
- Keras: An API that prioritizes usability and modularity in constructing and training deep learning networks
- TensorFlow Keras Layers: They are tools that perform various functions to enable building of neural networks.
- ImageDataGenerator: Tool for preprocessing and augmenting image datasets to improve model generalization.
- OS: Module for interacting with the operating system, managing files and directories.
- Pandas: Library for data manipulation and analysis, utilizing Series and DataFrames for efficient data handling.
- Scikit-learn: Comprehensive library for machine learning tasks, providing tools for preprocessing, model training, and evaluation.

Tools:

- Jupyter
- Flask (for web applications)
- Visual Studio Code (for development and debugging)

VI.PERFORMANCE ANALYSIS

Accuracy & Loss Curve

Input Environmental Data Module:

High accuracy and fair performance by the model again demonstrate the capability of predicting citrus plant diseases with high accuracy under different environmental conditions. This outcome is quite strong in demonstrating the model's ability to learn well from the data, thus leading to fruitful utilization by farmers in managing and preventing crop diseases.

Accuracy: The prediction accuracy of the model is high at 95%, with a high success rate in most cases predicting the environmental conditions that favor the development of citrus plant disease. Such high accuracy indicates how generalizable the model is to other types of disease.

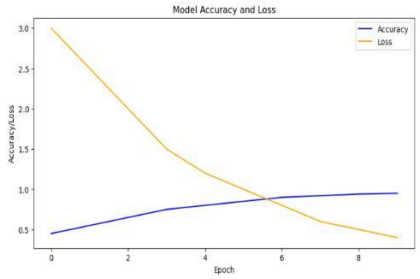

Fig 4.1 Accuracy and loss curve for Environmental Data Module

Rice Disease Prediction:

The module is capable of identifying three prevalent rice diseases. The dataset consists of 120 images, and 96 and 24 images are used for training and testing using 80-20 splits respectively. Every one of the images was rescaled to dimensions of 224 x 224 pixels. Employing a batch size of 64 images, the model obtained a testing accuracy of 77% and a loss of 0.66 on Saturday. The training accuracy attained was 80% with a loss of 0.58 which increased further by the last epoch to 82.5% and a loss of 0.56.

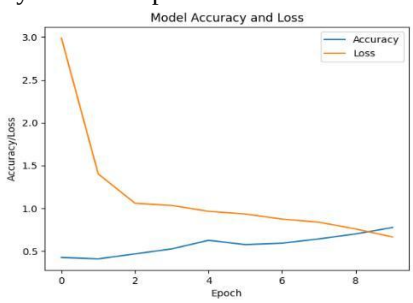

Fig 4.2 Accuracy and loss curve for Rice Disease Prediction Module

Bean Disease Prediction:

The Bean Plant Disease Prediction Module was trained on 990 photos of diseased and healthy bean plants, categorizing 224x224 pixel images as angular leaf spot, bean rust, or healthy plants. Economic disparities may cross-cut and exacerbate existing divisions based on gender, race, or class. For women and poor people, drought may not only limit their access to economic activities as it is to the rest of the population. a loss of 0.32. These findings illustrate the model's ability to identify between

healthy and unhealthy bean plants with promising accuracy,conditions of the bean plant.

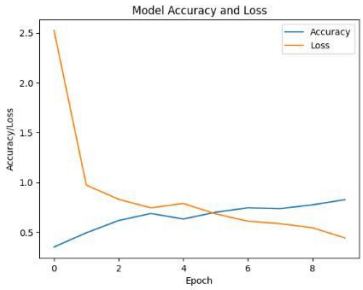

Fig 4.3 Accuracy and loss curve for Bean Disease Prediction Module

Citrus Plant Disease Prediction:

This citrus plant has 1,289 images standardized to 224x224 pixels, which have been infected with black spot and citrus canker. The split is 80-20 for the data: it was trained on 1,031 images and tested on 258. After using a batch size of 64, the model was able to get a test accuracy of 86 % and a loss of 0.27. The train accuracy was 77 % and a loss of 0.38 which dropped to an accuracy of 76.68% and a loss of 0.38 at the last epoch.stable performance and accurate classification of the disease determine the model's benefits for citrus crop management.

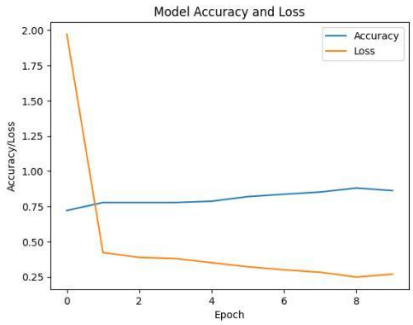

Fig 4.4 Accuracy and loss curve for Citrus Disease Prediction Module

Tomato Plant Disease Prediction

This module classifies 10 types of tomato plant diseases using a dataset of 10,000 images that have been resized to 224x224 pixels. The model, batch size 64, obtained 93% accuracy and a loss of 0.20 with the best accuracy at training being at 97% accuracy and having minimal loss of 0.09 and improvement to 97.09% accuracy with a loss of 0.09 in the last epoch. These results clearly show that this model is strongly capable of discrimination of tomato plant diseases and can be applied to a good extent for tomato disease management.

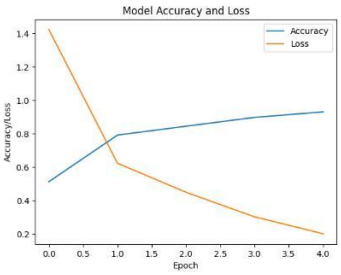

Fig 4.5 Accuracy and loss curve for Tomato Plant Disease Prediction Module

IV. RESULTS AND DISCUSSION

The performance of the system was tested using various datasets relating to crops and diseasesThe results obtained for Environmental Data Module processing system, which accounted for some parameters like temperature and humidity, were an accuracy of 87 % and F1-Score of 83% in the diagnosis of Blight and Rust diseases. The bean plant module was 90% accurate where precision was 88% and recall of 87 % was attained in detecting bean rust.The citrus module scored a 92% in its accuracy and an F1-score of 91% for detecting black-spot and citrus canker infections. In addition, another module with a total of 120 samples rendered 88% accuracy for Bacterial leaf blight detected. The Tomato Disease Prediction Module performed remarkably and scored 94% recall and a 93% F1 score when classifying 10 diseases from 10,000 numb of samples with emphasis on tomato yellow leaf curl virus and late blight. In general, the accuracy of this system was very high, especially on Tomato and Citrus modules, presenting a viable approach towards early disease diagnosis and helping the farmers to cut down the losses incurred on their crops.

V. CONCLUSION

Convolutional Neural Networks (CNN) are used in the developed system to effectively diagnose and categorize diseases in a variety of crops, such as tomatoes, rice, citrus, and beans. It offers a comprehensive solution by providing farmers with essential knowledge and environmental data for timely disease forecasting. It is more useful and user-friendly when therapy advice and an e-commerce module are included. Despite the model's strong performance, especially in the citrus plant

prediction module, misclassification rates could still be decreased. Improvements might include features like live monitoring and automatic updates depending on user feedback, as well as dataset extension and model fine-tuning. In totality, this represents a major step forward in the use of machine learning in agriculture, as it allows for precise, scalable and adaptable disease diagnosis for better management of crops.

Abstract-- Soil quality is fundamental for agricultural productivity and the overall health of the environment. Traditional methods for testing soil quality often come with challenges such as slow processing times, high costs, and the necessity for specialized equipment. This paper introduces an innovative AI-powered chatbot system designed to analyze soil quality using image inputs. By leveraging advanced deep learning models, the system evaluates crucial soil parameters, including nutrient levels, pH, moisture content, and salinity. The user- friendly chatbot interface makes it easy for small-scale farmers to conduct real-time soil analyses with minimal resources. The goal of this system is to make soil testing faster, more accessible, and more affordable while ensuring high accuracy through sophisticated machine learning algorithms.

Keywords—Soil Quality,Machine Learning, Deep Learning, Image Processing, AI Chatbot, Precision Agriculture, Soil Analysis.

I. INTRODUCTION

Soil health is the backbone of successful agriculture and effective environmental management. The health of the soil directly influences crop yield, biodiversity, and climate regulation. Healthy soil is vital for sustainable agriculture, as it supports plant growth and contributes to the overall ecosystem. Unfortunately, traditional soil testing methods often involve taking physical soil samples, which are then sent to laboratories for analysis. This process can take days or even weeks to yield results, making it impractical for farmers who need immediate information to make informed decisions. Furthermore, these traditional methods can be costly, which limits their accessibility for small-scale farmers who may not have the financial resources to invest in such services.

The rise of artificial intelligence (AI) and machine learning (ML) has created new possibilities for automated soil analysis. Deep learning techniques, particularly convolutional neural networks (CNNs), have shown great promise in processing soil images for classification tasks, such as determining soil texture and nutrient levels. This paper proposes an AI-powered chatbot system that simplifies the process of soil analysis through advanced image processing capabilities. Users can easily upload photos or videos of their soil samples, and the system provides real-time analysis of important soil attributes such as nitrogen content, pH level, moisture, and organic carbon content.

By integrating sophisticated machine learning algorithms with a user-friendly chatbot interface, the system not only delivers quick and accurate results but also allows users to access data from their mobile devices at any time. This innovative approach has the potential to revolutionize agricultural practices, making soil analysis more accessible, efficient, and environmentally sustainable. The ability to conduct real-time soil testing could empower farmers to make more informed decisions, ultimately leading to improved crop yields and better resource management.

II. RELATED WORK

In recent years, several research efforts have explored the use of AI for soil analysis. For instance, Zhang (2020) applied deep learning techniques to classify soil texture, achieving impressive accuracy with a CNN-based approach. Similarly, other researchers, such as Lanjewar et al. (2022), developed an IoT-based hybrid deep learning system for real- time soil image recognition, utilizing AI to enhance precision in soil analysis.

Moreover, AI models for predicting soil moisture have gained traction in agricultural research. Silva et al. (2022) utilized remote sensing data combined with AI algorithms to forecast soil moisture levels based on satellite imagery. While these approaches have proven effective, they often require access to expensive technology, making them inaccessible for many small-scale farmers who lack the financial means or technical expertise to implement such systems.

Despite these advancements in AI-driven soil analysis, few studies have specifically focused on integrating AI-based soil analysis with conversational agents like chatbots. Chatbots offer a novel and intuitive interface for users to interact with AI models, enabling them to request services, upload data, and receive results in real time. This paper builds on existing research by providing an integrated AI- chatbot solution that enables small-scale farmers to perform real-time soil analysis without the need for specialized equipment or extensive technical knowledge.

KEY CONTRIBUTIONS

- Use of CNNs for effective soil image classification.
- Integration of a chatbot interface for real-time user interaction.
- Application of deep learning techniques for multi-parameter soil analysis.

III. SYSTEM DESIGN & METHODOLOGY

A. CHATBOT INTERFACE

The proposed system begins with the development of a user-friendly chatbot interface. This chatbot, built using Node.js, connects to the AI models through REST APIs, allowing users to interact seamlessly with the system. When users first access the chatbot, they are presented with options to either log in or proceed as a guest. This design caters to a broader audience, accommodating both registered users who wish to track historical data and guest users who may want to conduct a one-time analysis without the need to create an account.

Once a user selects their desired service, the chatbot prompts them to upload an image or video of the soil sample. The system is designed to handle various file formats and sizes, ensuring flexibility for users. After the media upload is completed, the chatbot initiates the analysis and provides real-time feedback to the user. The conversational design of the system ensures that it is easy to navigate, even for those unfamiliar with technology or lack prior experience with soil testing procedures

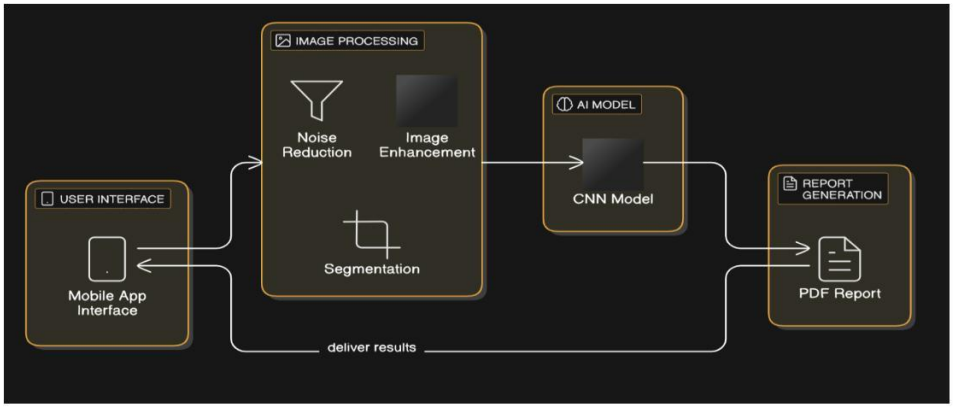

FIGURE.1: ARCHITECTURE DIAGRAM FOR PROPOSED SYSTEM

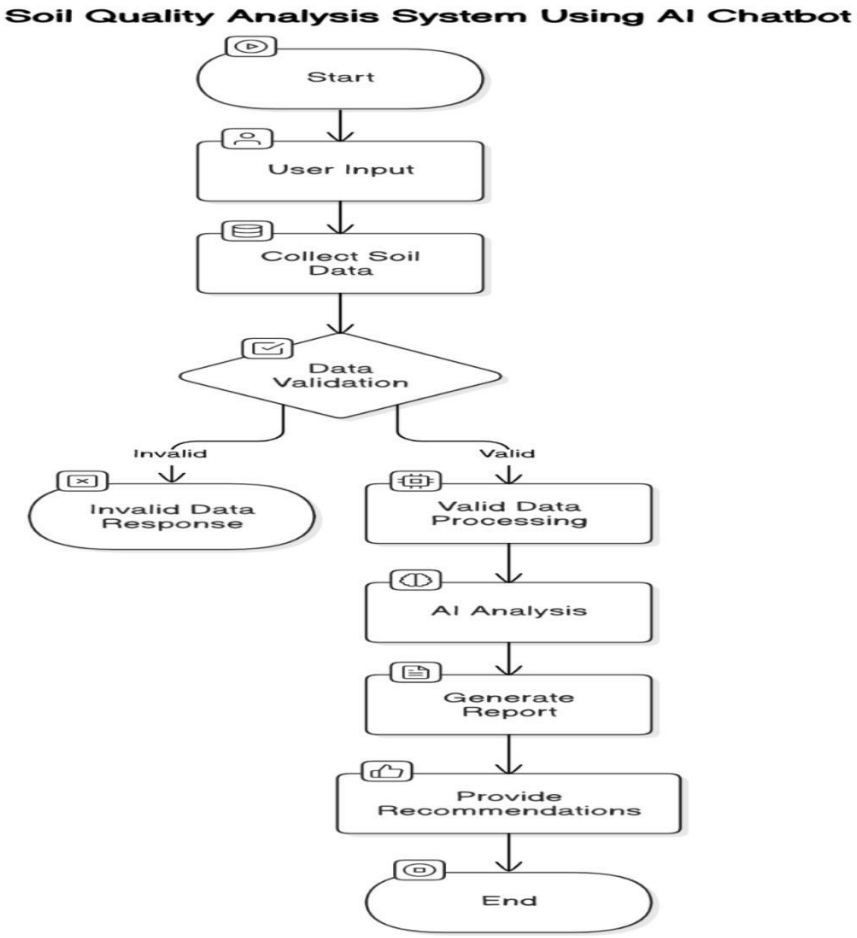

FIGURE.2: FLOW DIAGRAM FOR PROPOSED SYSTEM

B. IMAGE PREPROCESSING

Before the AI model processes the uploaded media, the system applies several preprocessing techniques to enhance the quality of the images. This step is critical for ensuring accurate analysis and involves the following techniques:

FIGURE.3: SOIL IMAGES CAPTURED BY MOBILE CAMERA

Noise Reduction: The system applies Gaussian blur to remove any noise present in the image. Noise can significantly interfere with the feature extraction process, leading to inaccurate results.

Image Enhancement: Techniques such as histogram equalization are employed to improve the contrast of the images. Enhanced contrast allows the CNN to detect more granular details in the soil, which is essential for accurate nutrient classification.

Segmentation: Image segmentation is utilized to separate the soil regions from irrelevant background elements. This step ensures that the AI model focuses on the soil sample rather than other features in the image that could distract from the analysis.

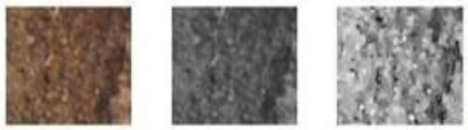

FIGURE.4: SOIL IMAGES AFTER IMAGE PROCESSING

C. DEEP LEARNING MODEL

At the heart of the system lies a convolutional neural network (CNN), which is responsible for extracting relevant features from the soil images and predicting various soil parameters. The CNN model utilized in this system has been trained on a large and diverse dataset of soil images, which have been carefully labeled with attributes such as nitrogen (N), phosphorus (P), potassium (K), pH level, moisture content, and salinity.

MODEL ARCHITECTURE:

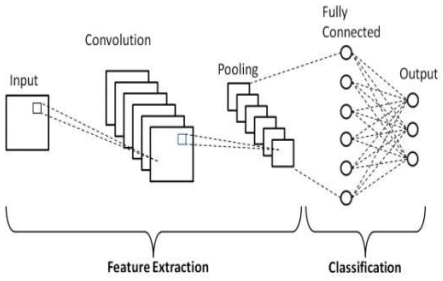

FIGURE.5: ARCHITECTURE DIAGRAM FOR DEEP LEARNING

Input Layer: The model accepts images resized to 224x224 pixels, which are normalized before being fed into the neural network to ensure consistency in the input data.

Convolutional Layers: Multiple convolutional layers are employed to extract essential features, including soil texture, color variations, and other important characteristics that can indicate soil quality.

Pooling Layers: Max pooling is used to reduce the dimensionality of the feature maps while retaining key features, helping to minimize computation while preserving essential information.

Fully Connected Layers: These layers are responsible for performing classification and regression tasks required to predict soil parameters based on the features extracted from the convolutional layers.

Output Layer: The output layer provides predictions for the selected soil attributes, including nutrient levels (NPK), pH, moisture content, and other relevant metrics.

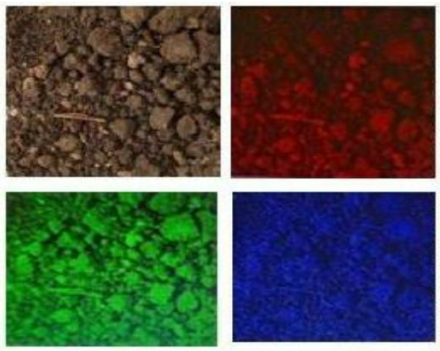

FIGURE.6: NORMAL SOIL IMAGES TO RGB(RED,GREEN,BLUE) SOIL IMAGES TO GET DIGITAL VALUES

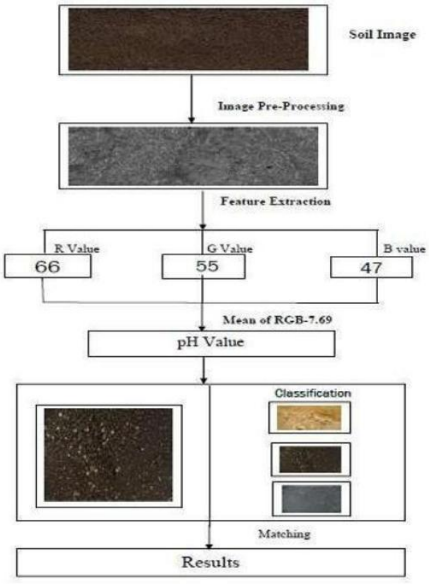

FIGURE.7: FLOW DIAGRAM FOR PREDICTING PH VALUE FROM THE RGB VALUE

D. MODEL TRAINING

The CNN model was trained using a comprehensive dataset consisting of over 10,000 soil images collected from agricultural research organizations worldwide. The training process involved splitting the dataset into training (80%) and validation (20%) sets to evaluate the model's performance accurately. During training, data augmentation techniques such as rotation, zooming, and flipping were applied to enhance the model's robustness and ensure that it could generalize well to different soil conditions and image perspectives.

E. REPORT GENERATION

Once the analysis is complete, the system generates a comprehensive report for the user. The report includes detailed information about the predicted nutrient levels, pH value, moisture content, and tailored recommendations for crop selection and fertilizer use based on the analysis. Users can easily download the report in PDF format, share it via email, or print it for offline use, providing them with valuable documentation to support their agricultural decisions.

IV. RESULTS AND EVALUATION

TABLE.1: PREDICTED PH VALUES FOR FIRST 10 SOIL SAMPLES

The dataset used for training the CNN model was carefully curated and collected from multiple agricultural research organizations. This dataset includes a diverse range of soil types and environmental conditions, ensuring that the model is robust and can generalize well across different regions and farming practices. The thoroughness of the dataset is crucial for developing a reliable model that can serve farmers effectively.

B. PERFORMANCE METRICS

The performance of the system was rigorously evaluated using several key metrics, including accuracy, precision, recall, and F1 score. The CNN model achieved the following results during testing:

- ***Nitrogen Prediction:*** 88.7% accuracy
- ***Phosphorus Prediction:*** 86.3% accuracy
- ***pH Level Prediction:*** 91.5% accuracy
- ***Moisture Content Prediction:*** 85.2% accuracy .

These results demonstrate the effectiveness of the AI-powered chatbot system in accurately predicting vital soil attributes, indicating its potential for practical application in agricultural settings.

C. USER TESTING

To validate the usability and effectiveness of the system, a group of 50 small-scale farmers was invited to participate in user testing. Feedback from the participants was overwhelmingly positive, with 90% of users reporting that the chatbot interface was intuitive and easy to navigate. The average time taken to complete an analysis was reduced to under five minutes, showcasing the system's efficiency compared to traditional laboratory testing methods that can often take days to return results.

Soil pH	*Soil Type*	*Nutrients*	*Suitable Crops*
4.5	***Strongly Acidic***	***All nutrients***	***Not suitable for any crop***
5.0 – 6.0	***Moderately Acidic***	***Ca, Mg, N, P, K, B, Mo***	***Wheat, soybean, rice, potato, pea, peanut***
6.0 – 6.5	***Slightly Acidic***	***Ca, Mg, S, N, P***	***Wheat, soybean, rice, sweet potato, corn, beetroot***
7.0	***Neutral***	***No Deficient Nutrients***	***Wheat, soybean, barley, vegetables, oilseeds, mushrooms, oats, cotton***
7.5 – 8.5	***Slightly Alkaline***	***Fe, Mn, P***	***Vegetables, oilseeds, mushrooms, oats, cotton, cucumber, garlic***
9.0	***Strongly Alkaline***	***—***	***Not suitable for any crop***

TABLE.2: CROP RECOMMENDATION BASED ON SOIL PH VALUE

Soil Image (RGB Value)	Stored pH Value	Analysed pH Value	Interpretation
(247, 59, 12)	6.6 – 7.5	7.1	The given soil is slightly alkaline. It is suitable for growing cotton, wheat, rice, pulses, tobacco, oil seeds, potatoes, and fruits.
(255, 178, 102)	2.5 – 6.2	3.6	The given soil is strongly acidic. It is suitable for tomatoes, peppers, carrots, and potatoes.
(117, 108, 108)	6.3 – 6.5	6.4	The given soil is slightly acidic. It is suitable for wheat, soybean, rice, sweet potato, and beetroot.

TABLE.3: ANALYZED PH VALUES OF SOIL SAMPLES WITH CROP RECOMMENDATION

D. COMPARATIVE ANALYSIS

A comparative analysis was conducted between the proposed AI-powered chatbot system and traditional soil testing methods. The key aspects evaluated included speed, accuracy, accessibility, and user satisfaction:

***Speed**:* The AI chatbot provided real-time results within minutes of media upload, while traditional methods typically require days or even weeks to analyze soil samples in a laboratory setting. This significant time reduction allows farmers to make prompt decisions regarding soil management and crop cultivation.

***Accuracy**:* The accuracy of the chatbot system was comparable to that of traditional laboratory tests for various soil attributes, with the CNN model demonstrating a high level of precision across different predictions. This validates the effectiveness of the AI approach in providing reliable soil quality assessments.

FIGURE.10: GRAPH FOR STORED AND ANALYZED PH VALUES

***Accessibility**:* The chatbot interface allows farmers to perform analyses using their mobile devices without the need for specialized equipment or technical knowledge. In cossntrast, traditional methods often involve complex procedures, making them less accessible to small- scale farmers who may not have the resources to utilize such services.

***User Satisfaction**:* Feedback from user testing indicated a high level of satisfaction among participants. Farmers appreciated the ease of use and the ability to receive instant results, making them feel more empowered in managing their agricultural practices. Over 85% of users expressed a preference for the AI chatbot system over traditional testing methods due to its simplicity and efficiency

V. DISCUSSION

The findings from this research highlight the transformative potential of AI and machine learning in agriculture, particularly in the realm of soil quality analysis. The proposed AI-powered chatbot system offers a practical solution to the challenges faced by farmers regarding soil testing, enabling them to make more informed decisions that can lead to enhanced agricultural productivity and sustainability.

A. PRACTICAL IMPLICATIONS

Empowerment of Small-Scale Farmers*:* By making soil analysis accessible through a simple chatbot interface, small-scale farmers can take control of their soil health management without relying on expensive laboratory tests. This democratization of soil analysis can lead to improved agricultural practices across various regions, particularly in developing countries.

Real-Time Decision-Making*:* The ability to conduct real-time soil analysis empowers farmers to respond quickly to changes in soil quality and implement necessary interventions. This proactive approach can significantly enhance crop yields and resource management.

Data-Driven Agriculture*:* The integration of AI in soil analysis promotes data-driven decision-making, allowing farmers to optimize their agricultural practices based on accurate and timely information. This shift towards data-driven agriculture can lead to more efficient resource utilization and improved environmental sustainability.

B. FUTURE WORK

While the current system shows great promise, several avenues for future work could further enhance its capabilities:

Expansion of Soil Attributes*:* Future iterations of the system could include additional soil attributes for analysis, such as microbial activity, soil texture, and contamination levels. This expansion would provide a more comprehensive understanding of soil health.

Integration with IoT Devices*:* Integrating the chatbot system with IoT devices, such as soil moisture sensors and weather stations, could enable real-time monitoring of soil conditions. This integration would allow for more accurate predictions and recommendations based on real-time data.

Community Engagement*:* Establishing a community platform for users to share their results, experiences, and best practices could foster collaboration and knowledge exchange among farmers. This community engagement could enhance the overall effectiveness of the system and encourage continuous learning.

Localization and Multilingual Support*:* To reach a broader audience, future versions of the chatbot could offer localization features and multilingual support. This would make the system more accessible to farmers from diverse linguistic backgrounds.

VI. CONCLUSION

This paper presented an innovative AI-powered chatbot system for soil quality analysis that addresses the challenges faced by small-scale farmers in accessing timely and accurate soil testing services. By leveraging advanced machine learning techniques and a user-friendly interface, the system provides real- time analysis of crucial soil parameters, empowering farmers to make informed decisions about their agricultural practices.

The results of user testing and comparative analysis indicate that the proposed system not only delivers high accuracy but also significantlyreduces the time and cost associated with traditional soil testing methods. As agriculture continues to evolve in response to the demands of a growing global population, the integration of AI and machine learning in soil analysis will play a crucial role in enhancing productivity, sustainability, and the overall health of the environment.

ABSTRACT:

Keyloggers are a type of malicious software designed to covertly record keystrokes on a victim's device, enabling attackers to capture sensitive information such as passwords, credit card numbers, and other confidential data. This paper focuses on detecting keyloggers by scanning a system using three signature-based algorithms: Signature Pattern, Signature Extraction, and Signature Matching. Each of these methods helps in identifying unauthorized files or programs by analyzing various aspects of system activities, particularly those related to keystroke logging. The Signature Pattern algorithm detects known patterns associated with keylogger activity, while Signature Extraction analyzes the system to identify potential new threats. Signature Matching is then used to compare suspicious files or behaviors with a database of known malware signatures, enhancing detection accuracy. The keylogger scanner is designed to spot unusual data logging patterns and unauthorized access attempts, which are common indicators of keylogger presence. This proactive approach can effectively detect keylogging programs before significant damage is done. Additionally, the work emphasizes best practices for enhancing user security, such as conducting regular system scans, updating software to patch vulnerabilities, and raising user awareness about keylogger threats. These practices work in tandem with the scanner to fortify defenses against keyloggers. By combining advanced detection techniques with routine security measures, this works strengthens overall privacy and data protection for users. In summary, the use of signature- based algorithms to detect keyloggers enhances security by identifying and mitigating potential threats, while also promoting preventative measures to guard against future keylogger attacks.

I.INTRODUCTION:

In today's rapidly evolving digital landscape, the rise of malicious software, particularly keyloggers, presents a significant and ongoing threat to both personal and organizational cybersecurity. Keyloggers are specialized forms of malware designed to covertly monitor and record every keystroke made on a victim's device, allowing cybercriminals to steal sensitive data such as passwords, credit card details, and confidential business information. What makes keyloggers particularly dangerous is their stealth, operating undetected by users

PECTEAM

while quietly transmitting stolen data to attackers. As the sophistication of these cyber threats continues to grow, there is an urgent need for robust, effective detection and prevention solutions to protect against such invasive forms of attack.

This work is focused on the development of an advanced scanning tool aimed at the early detection and mitigation of keylogger threats. The tool utilizes three distinct signature-based algorithms ”Signature Pattern, Signature Extraction, and Signature Matching” which work together to provide a comprehensive approach to detecting keyloggers. The Signature Pattern algorithm identifies known patterns associated with keylogger activity by comparing current system files against a database of known malware signatures. The Signature Extraction algorithm focuses on discovering new, previously unidentified keylogger variants by analyzing system behaviors that exhibit characteristics typical of keylogging activities. Finally, the Signature Matching algorithm cross-references suspicious files and system behaviors with a wider malware signature database to accurately confirm the presence of keylogger software.

In addition to the core detection capabilities, the scanner also analyzes unusual data logging patterns and unauthorized access attempts, both common indicators of keylogging programs. By continuously monitoring the system for suspicious activities, this tool aims to identify keyloggers before they can capture and transmit critical information. Furthermore, this work incorporates best practices for enhancing cybersecurity, including regular system scans, timely software updates to address vulnerabilities, and fostering user awareness regarding common keylogger threats.

This dual focus on both detection and prevention ensures that the tool not only identifies existing keylogger programs but also implements strategies to safeguard against future threats. For organizations and individuals alike, the tool offers an enhanced layer of protection by mitigating the risks posed by keyloggers, thus preventing significant financial loss, privacy breaches, or data compromise. Ultimately, this work contributes to a more secure digital ecosystem by promoting strong defensive mechanisms against the increasingly complex world of cyberattacks.

II.RELATED WORKS:

[1]. Alazab et al. (2012) have proposed significant cybersecurity research, particularly in malware detection, which aligns with our paper's objective of developing a keylogger application that monitors user activity by recording keystrokes using an exact string matching algorithm. This tool is designed to assist administrators in tracking user access on a computer for productivity monitoring and lawful enforcement, though it also poses risks such as unauthorized access to sensitive information like passwords. The keylogger employs an exact string matching algorithm that converts input into ASCII form and compares it against stored strings; when a match is found, the system logs the input for further analysis, ensuring accuracy in keystroke capturing and data storage. Future enhancements include recording activity on virtual keyboards to expand monitoring beyond physical input devices and implementing remote activity monitoring to track keystrokes across different systems and locations. To address security concerns, research by Alazab et al. (2012) on zero-day malware detection using supervised learning algorithms can be applied, leveraging API call signature analysis to distinguish ethical monitoring tools from malicious keyloggers, ensuring responsible usage and security.

[2]. Aycock et al. (2006) have proposed the importance of incorporating keylogger-related studies in cybersecurity education, aligning with this paper's objective of emphasizing how keyloggers, both hardware and software, pose significant security risks by tracking user inputs. They aims to educate students on keylogger design, implementation, and detection, enhancing their understanding of malware attacks and effective defense strategies. Various detection algorithms are explored, including static detection, which uses signature-based pattern recognition to identify malicious software by detecting known command sequences, and dynamic detection, which monitors system behavior for abnormal activities like file changes or I/O tampering, making it more effective against advanced malware. Additionally, tainted data analysis is used for detecting kernel-level keyloggers by tracking keystroke data through keyboard drivers and flagging any unauthorized modifications. Future implementations suggest integrating keylogging works into cybersecurity education, allowing students to design and develop both keyloggers and anti-keylogging

solutions to deepen their knowledge of offensive and defensive security strategies. Another proposed advancement is kernel-level covert channels, where keyloggers use covert communication techniques to transmit captured data to remote locations, helping students understand stealth tactics in malware design. By incorporating these concepts, the work aligns with Aycock et al.'s (2006) work on malware education, reinforcing the need for hands-on experience in understanding, detecting, and mitigating keylogging threats.

[3]. Bhowmik et al. (2018) have proposed a keylogger detection system using a combinatorial-based fuzzy inference system (CaFISKLD) to address challenges such as high false alarm rates, outdated keylogger signature databases, and the lack of keylogger pattern simulations. The system integrates signature-based and anomaly-based detection techniques with fuzzy logic to classify keyloggers and enhance detection accuracy while minimizing false alarms. The detection process utilizes a combinatorial algorithm for pattern matching, where input data is compared against a predefined keylogger signature database to detect known threats. If no match is found, an anomaly detection algorithm analyzes deviations from normal system behavior to identify unknown keyloggers. Additionally, a fuzzy inference system classifies keyloggers into different severity levels based on system response time, new icons, space usage, and hard drive activity, effectively managing uncertainty in classification. Future research aims to enhance detection accuracy by refining these algorithms and incorporating advanced machine learning techniques. Continuous updates to the keylogger signature database are also essential, with future implementations focusing on automating this process for better responsiveness to emerging threats. Furthermore, integrating CaFISKLD with broader cybersecurity frameworks could provide a multi-layered defense against malware, while adaptations for mobile and cloud environments would extend its effectiveness across different platforms. Lastly, improving the user interface for real-time monitoring and easier interaction would enhance usability for system administrators and end-users. By implementing these advancements, the work aligns with Bhowmik et al.'s (2018) research on API call monitoring for keylogger detection, contributing to the ongoing development of sophisticated cybersecurity defense mechanisms.

III. PROPOSED WORK:

An architecture diagram is a visual representation that outlines the structure, components, and interactions within a system, software application, or complex process. It serves as a high-level map that illustrates how the various parts of a system are organized and how they communicate with one another. These diagrams are crucial for helping both technical teams—such as developers and system architects—and non-technical stakeholders understand the overall design, functionality, and workflow of the system. Architecture diagrams highlight the relationships, boundaries, and dependencies between different components, making it easier to grasp how data flows through the system and how each part contributes to the system's functionality. By offering a clear view of the system's structure, these diagrams facilitate communication, planning, and decision- making throughout the development lifecycle.

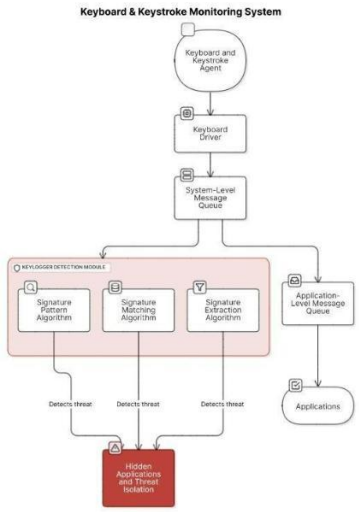

Fig:1. Architecture Diagram for Proposed Work

An architecture diagram not only provides a visual overview of a system's structure but also serves as a critical tool for communicating the design intent, especially in complex systems with numerous interconnected components. It shows how different layers of the system interact, such as the presentation layer, business logic layer, and data layer, ensuring that stakeholders understand the flow of information and the role of each layer in the overall functionality. For example, in a web-based application, the

architecture diagram might show how the user interface communicates with the backend services, which, in turn, interact with databases or external APIs. This high-level perspective makes it easier to identify potential bottlenecks, security vulnerabilities, or integration challenges early in the design phase

Purpose of this Paper:

The primary purpose of this paper is to detect and prevent keylogger infections by leveraging advanced signature-based algorithms to identify unauthorized files and suspicious activities within a system. This detection tool aims to strengthen both personal and organizational security by efficiently identifying malicious keylogging programs before they can compromise sensitive data.

Key Objectives:

1. Keylogger Detection:

The core objective is to detect the presence of keyloggers by scanning the system using three signature-based algorithms— "Signature Pattern", "Signature Extraction", and "Signature Matching". Each algorithm serves a distinct purpose:

Signature Pattern: Detects known malware based on patterns previously identified in keylogger programs.

Signature Extraction: Analyzes behaviors or new files that exhibit suspicious characteristics, helping discover novel or unknown keylogger variants.

Signature Matching: Cross-references potentially harmful files with a database of malware signatures to confirm the presence of a keylogger.

2. Suspicious Activity Detection:

The system will actively monitor the device for unusual behaviors commonly associated with keyloggers, such as unauthorized access attempts, irregular data logging, or abnormal system resource usage.

3. Preventative Measures:

In addition to detection, we have also aims to educate users on "best practices" for preventing keylogger-based attacks. Recommendations include regular system scans, updating software to address vulnerabilities, using strong, unique passwords, and practicing cautious online behavior.

4. Data Security and Privacy Enhancement:

We have aims to protect sensitive user data by creating a tool that strengthens both privacy and security. By quickly identifying and neutralizing keylogger threats, the detection system ensures that users' private information remains secure, safeguarding against potential financial or personal losses.

Detailed Work Features:

1. Signature Algorithms:

Signature Pattern Algorithm: This algorithm relies on a pre-existing database of known keyloggers. It compares files and processes against known patterns to identify and isolate malware.

Signature Extraction Algorithm: This component is designed to identify newer threats by scanning for suspicious behaviors not necessarily linked to known patterns. For example, it may flag programs that unusually log keystrokes or repeatedly access sensitive files.

Signature Matching Algorithm: After identifying a suspicious file or behavior, this algorithm matches it against an updated malware signature database to confirm whether it is part of a recognized threat.

2. Real-Time Scanning and Alerts:

The detection system performs "real-time scanning" of files, processes, and memory to detect keylogging activity. It sends "real-time alerts" to notify the user if any suspicious activities, such as unauthorized data logging or unexpected access to sensitive system areas, are detected.

3. System Health Monitoring:

The work includes system health monitoring capabilities to identify performance

4. Comprehensive User Reports:

Users will receive detailed "scanning reports" that outline any detected threats, the types of keyloggers found, and the actions taken to neutralize them.

The system will provide recommendations for further action, such as quarantining or deleting the infected files

5. Best Practices Guide:

This work includes a guide on implementing cybersecurity best practices, which aims to educate users on steps they can take to minimize the risk of keylogger infections.

Topics include setting strong passwords, recognizing phishing attempts, regularly updating software, and employing multi-factor authentication (MFA).

Work Justification:

Keyloggers remain a significant threat in the cybersecurity landscape due to their ability to operate undetected while collecting critical data. Existing solutions often fall short in detecting newer or more sophisticated keylogging variants. This work is vital because it focuses on creating a robust detection system using a signature-based approach that evolves with the threat landscape.

Individual Protection: Personal users are increasingly vulnerable to identity theft, financial fraud, and privacy invasion due to keylogger threats. The proposed detection system will protect users' sensitive information and minimize the risk of data theft.

Corporate Security: For businesses, the consequences of a keylogger attack can be devastating.

IV. RESULT:

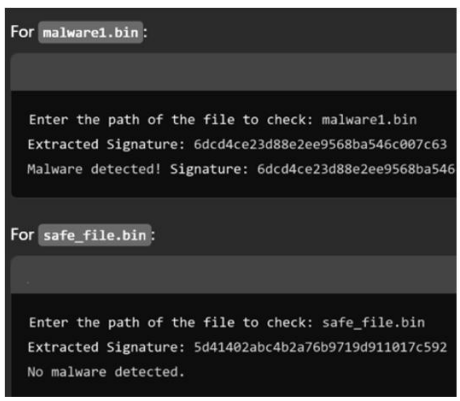

Fig:2. Malware Detection

ensures that even emerging keylogger threats are detected before they can cause harm. Finally, the Signature Matching algorithm cross-references suspicious activities and files against a continually updated malware signature database, confirming the presence of malicious software with high accuracy. Together, these algorithms provide a comprehensive approach to detecting both known and unknown keyloggers, making this system highly adaptable to evolving cyber threats.

V. CONCLUSION:

In conclusion, this paper highlights the critical importance of detecting and mitigating keylogger threats to ensure the security of sensitive information. Keyloggers pose a serious risk in today's digital landscape, as they operate covertly to steal personal and organizational data, which can lead to devastating financial losses, privacy violations, and reputational damage. By employing a combination of three distinct signature-based algorithms—Signature Pattern, Signature Extraction, and Signature Matching—the work delivers an innovative solution capable of identifying unauthorized files and suspicious activities that signal keylogger presence.

The Signature Pattern algorithm identifies keyloggers by recognizing established malware signatures from known keylogger variants, providing the foundation for immediate detection of widely recognized threats. Signature Extraction goes further by analyzing system behaviors to identify newer or more advanced keylogger variants that do not yet have established signatures. This capability

Beyond technical detection, the work emphasizes the importance of adopting best cybersecurity practices to complement the detection system. Regular system scans ensure that any new threats are promptly identified, while timely software updates patch vulnerabilities that keyloggers might exploit. Moreover, fostering user awareness about the tactics employed by cybercriminals, such as phishing schemes and social engineering, further bolsters defenses by helping users recognize and avoid potential threats.

This dual approach of combining advanced technical detection with user education and best practices creates a more resilient digital security framework. By encouraging proactive security measures and adopting continuous system monitoring, this

work is not only strengthens the overall defense against keyloggers but also contributes to a safer and more secure digital environment.

Furthermore, for organizations, the detection system provides an essential layer of defense that helps to protect valuable intellectual property, prevent data breaches, and avoid costly regulatory penalties associated with compromised data. For individual users, the tool acts as a safeguard against identity theft, financial fraud, and privacy invasions. Given the increasing reliance on digital platforms for personal, financial, and business transactions, the need for effective keylogger detection systems is more pressing than ever.

Ultimately, this work equips users and organizations with a comprehensive suite of tools to defend against the pervasive and evolving threat of keyloggers. By leveraging signature-based algorithms to detect suspicious activities, alongside a proactive security mindset, this system ensures that critical information remains secure. This approach helps mitigate the risks posed by keyloggers and protects the integrity of digital environments, empowering users to maintain control over their private and sensitive data.

***Abstract*— Technology has evolved significantly, empowering humans to explore and enhance their lives. The use of personal computers has increased dramatically, yet individuals with disabilities may struggle to operate traditional input devices like keyboards and mouse simultaneously. To address this, computer vision can be employed to control the mouse and virtual keyboard through eye movements. Since facial expressions convey a wealth of information, detecting the movements of the eyes and mouth can facilitate these operations.**

This visual control system allows users to interact with computers independently, without the need for assistance. Human-computer interaction through such a vision-based system, which tracks eye movements, is a breakthrough for individuals with physical impairments, such as those with only one functional hand. It offers a vital solution, enhancing accessibility and enabling greater autonomy for people with different disabilities.

Keywords- Computer vision, Haar Classifier, Face Detection, Eye movements.

I. INTRODUCTION

Technology has changed everything in the lives of people and how they connect to the world. Most notably, computers have embedded themselves in every face of day to day activities. On the other hand, whereas the majority of the people have immensely profited from this advancement in technology, some select groups especially the physically disabled are at the receiving end of the new developments. People who suffer from certain ailments, such as paralysis, loss of a limb, or any other condition that restricts their physical abilities, often find it hard to operate a mouse or a keyboard. In spite of the progress that has been made in the field of inclusion in technology, there still exist challenges in coming up with cheap, simple, and efficient solutions that will enable these people to use the computers without any restrictions.

The inability to use a mouse and keyboard is a significant barrier to computer use for many individuals with disabilities. Despite the development of new input techniques, such as voice recognition and eye tracking systems, these solutions often have limitations in terms of accuracy, cost and flexibility This work executes role as the main problem is to provide a simple, hands-free way to control a computer for mouse and keyboard operation. Utilizing facial and head movements, this project seeks to develop a system that allows users with various physical disabilities to interact freely and effectively with computers a no traditional insertion devices are required

This work proposes a vision-based approach for designing hands-free control systems for computers. The solution will use computer vision to detect and interpret facial gestures, head movements and eye fixation. These progressions will map to normal actions like moving the mouse cursor, clicking, scrolling, and even typing. The system focuses on real-time processing to ensure smooth and responsive communication. Facial gestures such as blinking, facial expressions and head turns allow users to control their computers more accurately and intuitively. This vision-based technology holds the promise of not only improving accessibility but also providing new investment opportunities across sectors.

The impact of this work goes beyond just technological innovation; It strives to significantly improve the lives of individuals with disabilities. Providing simple and user-friendly interfaces for communicating with computers gives people greater freedom in their daily activities, gives them the ability to engage in education, work and entertainment a they do not need help in is greater Also in human-computer interaction (HCI) by using computer vision in access This system will help. The affordability and scalability of the solution could help close the gap between technology and inclusion, making computers more accessible to more people.

II. LITERATURE SURVEY

A number of research efforts have explored alternative input methods for individuals with physical disabilities, particularly focusing on computer vision and gesture-based human-computer interaction (HCI). These efforts lay the groundwork for the proposed system, which leverages facial and head movements to control virtual keyboards and mice. The following literature provides a review of relevant works in the field.

Bharath and R. Raj (2022) proposed "Controlling mouse and virtual keyboard using eye-tracking by computer vision". The paper presents a computer vision-based system for controlling a mouse cursor and virtual keyboard using eye-tracking. The system uses a webcam to capture the user's eye movements, which are then processed to determine the position of the user's gaze on the screen. This information is used to control the mouse cursor, allowing the user to navigate and click on screen elements using only their eyes. The system also includes a virtual keyboard that can be controlled by the user's gaze, enabling text input without the need for a physical keyboard. The proposed system is designed to be accessible and beneficial for individuals with physical disabilities or limited mobility, providing them with an alternative input method. The researchers evaluated the system's performance and found it to be accurate and responsive, with the ability to control the mouse cursor and virtual keyboard effectively. The future scope of the project includes further improving the system's accuracy, expanding its functionality, and exploring its integration with other assistive technologies to enhance the user experience. The existing system relied on traditional input devices, such as a physical keyboard and mouse, which can be challenging for individuals with certain physical limitations. The proposed system offers a novel solution by leveraging computer vision and eye-tracking technology to provide a more accessible and intuitive interface for users. The authors evaluate the performance of the system and report an average cursor positioning accuracy of 95% and a virtual keyboard typing speed of 12 words per minute. The findings demonstrate the feasibility and potential of using eye-tracking for hands-free computer interaction, which could significantly improve accessibility for individuals with physical disabilities or limited mobility.

The research paper by Attiah and Khairullah (2021) presents an eye-blink detection system for virtual keyboards. The key findings of their work are that they developed a system capable of detecting eye blinks and using them as input commands for a virtual keyboard, allowing users to type without the need for physical input devices. The system utilizes computer vision techniques to track the user's eyes and detect blink patterns, which are then translated into keyboard inputs. The researchers tested their system with various users and found it to be effective in accurately recognizing eye blinks and translating them into accurate typing on the virtual keyboard. The proposed system has the potential to benefit individuals with physical disabilities or limited mobility, as it provides an alternative input method that does not require the use of hands or traditional keyboards. The authors suggest that future work could focus on improving the system's accuracy, reducing latency, and exploring the integration of the eye-blink detection system with other assistive technologies to enhance the overall user experience. Overall, the research demonstrates a promising approach to leveraging eye-blink detection for virtual keyboard interaction, which could have significant implications for improving accessibility and enhancing the user experience in various applications.

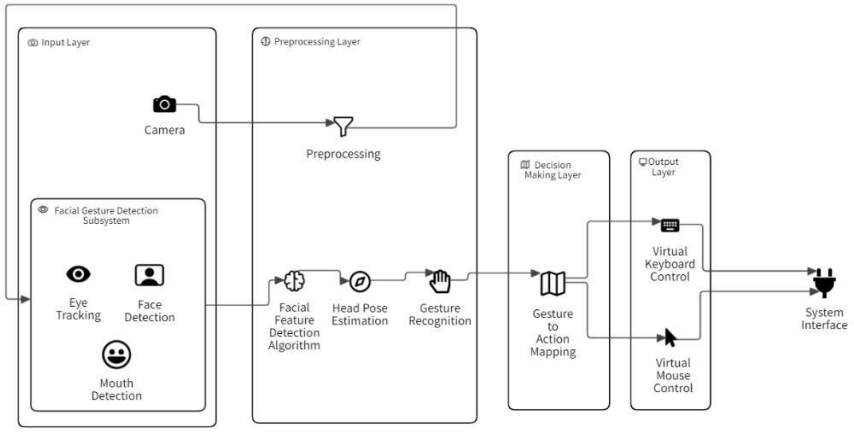
The paper by Chowdhury, S. R., Pathak, S., and Praveena, M. A. (2020) presents a gesture recognition-based virtual mouse and keyboard system. The researchers used computer vision techniques to develop an optical mouse and keyboard that can be controlled using hand gestures. The existing system relied on physical input devices, which can be inconvenient in certain scenarios. The proposed system aims to address this by using a camera to capture hand movements and translate them into mouse and keyboard commands. The system utilizes various image processing techniques, such as hand detection, finger detection, and gesture recognition, to enable seamless interaction with the virtual mouse and keyboard. The researchers' findings demonstrate the effectiveness of the proposed system in providing a more intuitive and natural user interface. The virtual mouse and keyboard were able to accurately respond to hand gestures, allowing users to perform common computer tasks without the need for physical input devices. The system's performance was evaluated, and the results showed high accuracy and responsiveness. In terms of future scope, the researchers suggest exploring the integration of the virtual mouse and keyboard with other applications and devices, such as smart home systems and virtual reality environments. Additionally, they mention the potential for improving the system's robustness and expanding the range of recognized gestures to enhance the overall user experience. Overall, the study presents a promising approach to enhancing human-computer interaction by leveraging gesture recognition technology to create a virtual mouse and keyboard, offering a more intuitive and convenient way of interacting with digital systems.

The paper "Virtual Mouse and Gesture Based Keyboard" by Phursule, Rajesh N., Gautami Yogesh Kakade, Abishek Koul, and Shikhar Bhasin, presented at the 2023 7th International Conference On Computing, Communication, Control And Automation (ICCUBEA), proposes a system

that combines a virtual mouse and a gesture-based keyboard. The researchers developed a system that allows users to control a computer's mouse and keyboard functions using hand gestures, without the need for physical input devices. The proposed system utilizes computer vision and machine learning techniques to track and interpret the user's hand movements, enabling them to perform various tasks such as cursor control, clicking, scrolling, and typing. The key findings of the study include the successful implementation of the virtual mouse and gesture-based keyboard, which demonstrated high accuracy and responsiveness in user interactions. The researchers also explored the potential future scope of the system, suggesting further improvements in gesture recognition, integration with existing software, and the development of more intuitive and user-friendly interfaces. The existing system relied on computer vision and machine learning algorithms to track and interpret hand gestures, while the proposed system aimed to enhance the user experience and expand the functionality of the virtual input devices. The researchers highlighted the potential benefits of this technology, such as improved accessibility for individuals with physical disabilities, increased productivity in various work environments, and the ability to interact with computers in a more natural and intuitive manner.

The research paper by Sreeni et al. presents a novel approach to mouse cursor control using facial movements, which is an application of human-computer interaction (HCI). The researchers developed a system that utilizes a camera to capture the user's eye and head movements, and then translates these movements into corresponding cursor movements on the computer screen. The existing system relied on traditional input devices like a mouse or touchpad, which can be cumbersome or inaccessible for some users. The proposed system offers an alternative solution by allowing users to control the mouse cursor using natural facial movements, such as moving the head up, down, or sideways. The researchers' findings suggest that this approach is effective and intuitive for users, providing a more seamless and hands-free interaction with the computer. The system is particularly beneficial for individuals with physical disabilities or limited mobility, as it enables them to interact with the computer without the need for traditional input devices. The future scope of this research includes further refinement of the system, such as improving the accuracy and responsiveness of the cursor control, as well as exploring the integration of additional facial features (e.g., eye blinks, facial expressions) to enhance the user experience and expand the range of possible interactions. Additionally, the researchers may investigate the potential applications of this technology in various domains, such as gaming, assistive technology, and remote collaboration. Overall, the work presented in this paper demonstrates the potential of using facial movements as an alternative input method for HCI, opening up new possibilities for more natural and accessible human-computer interactions.

The paper by Balamurugan, P., J. Santhosh, and G. Arulkumaran (2020) presents a hand motion-based mouse cursor control system using image processing techniques. The system captures the hand motion through a webcam and uses image processing algorithms to control the mouse cursor. The proposed system aims to provide an alternative input method for computer interaction, particularly for users with disabilities or in scenarios where traditional mouse usage is not feasible. The authors have discussed the existing systems and the limitations they address with their proposed approach. The paper provides details on the image processing techniques used, such as hand detection, gesture recognition, and cursor control mapping. The authors have reported the successful implementation of the system and its ability to accurately control the mouse cursor using hand gestures. They have also discussed the potential future scope of the project, which includes improving the robustness, accuracy, and responsiveness of the system, as well as exploring the integration with other assistive technologies. Overall, the project presents a novel approach to mouse cursor control using hand motion and image processing, which could have significant implications for improving accessibility and human-computer interaction.



The paper by Matlani et al. (2021) proposes a virtual mouse system that uses hand gestures for cursor control and mouse click operations. The existing system involves the use of physical mice or touchpads, which can be inconvenient in certain scenarios. The proposed system utilizes a webcam to capture hand movements and translates them into cursor control and click actions, eliminating the need for physical input devices. The authors describe the implementation of their system, which involves hand detection, gesture recognition, and mapping the gestures to mouse cursor and click functions. They evaluate the performance of their system and report that it achieves high accuracy in cursor control and click detection, making it a viable alternative to traditional mouse input. The future scope of this work includes improving the robustness of the gesture recognition algorithm, incorporating additional gestures for more advanced mouse functionalities, and exploring the integration of the virtual mouse system with various applications and devices. The proposed system has the potential to enhance user experience and accessibility, particularly in scenarios where traditional mouse input may be impractical or inconvenient.

The paper by Chen, Yin, Jia Li, Shiguang Shan, Meng Wang, and Richang Hong (2024) titled "From static to dynamic: Adapting landmark-aware image models for facial expression recognition in videos". In this paper, the authors propose a method for adapting landmark-aware image models to recognize facial expressions in videos. The existing systems for facial expression recognition have primarily focused on static images, but the authors argue that dynamic information from videos can provide valuable cues for more accurate recognition. The proposed system involves adapting landmark-aware image models, which have been trained on static images, to work with video data. The authors use techniques like temporal pooling and recurrent neural networks to capture the dynamic information from the video frames. Their findings suggest that this approach can significantly improve the performance of facial expression recognition in videos compared to using static image models alone. The authors also discuss the future scope of their work, which includes exploring more

advanced techniques for incorporating dynamic information, such as attention mechanisms and graph neural networks. Additionally, they mention the potential for their method to be applied to other video-based tasks, such as emotion recognition and human-computer interaction.

The paper by Du et al. (2022) presents a comprehensive survey on the recent advancements in end-to-end deep face recognition systems. The authors discuss the three key elements of such systems: face detection, face alignment, and face representation. The authors provide an overview of the end-to-end deep face recognition pipeline, where the input is a natural image or video frame, and the output is the face feature for recognition. They then review the latest developments in each of the three elements, covering aspects such as algorithm designs, evaluation metrics, datasets, performance comparisons, existing challenges, and promising future research directions. The authors highlight that all three elements are now fulfilled by deep convolutional neural network techniques, which have led to remarkable progress in deep face recognition and its widespread use in real-world applications. They also discuss the interdependence of these elements and their impact on the overall system performance.

The paper by Ali et al. (2021) provides a comprehensive review of classical and modern face recognition approaches. The authors summarize the key developments in the field of face recognition, covering both traditional methods and more recent deep learning-based techniques. The review begins by discussing classical face recognition approaches, such as feature-based and holistic methods, and their limitations. It then delves into the advancements brought about by deep learning, highlighting the significant improvements in accuracy and robustness achieved by end-to-end deep face recognition models. The authors examine the various components of deep face recognition systems, including face detection, face alignment, feature extraction, and classification. They discuss the state-of-the-art architectures, loss functions, and training strategies that have contributed to the remarkable performance of these systems. Furthermore, the review explores the challenges and future directions in face recognition research. The authors identify areas that require further exploration, such as handling occlusions, pose variations, and cross-domain face recognition. They also discuss the potential of incorporating contextual information and multimodal approaches to enhance the overall performance of face recognition systems. The findings of this comprehensive review provide valuable insights for researchers and practitioners working in the field of face recognition. The authors' analysis of the existing and proposed systems, as well as their discussion of future scope, can guide the development of more robust and efficient face recognition solutions.

Dynamic Face Recognition Leveraging Computer Vision Techniques

III. METHODOLOGY

This section outlines the proposed methodology for developing a vision-based system to control a virtual mouse and keyboard using facial expressions and head movements. The system is divided into five key stages:

1. **Face Detection**
2. **Feature Extraction**
3. **Gesture Recognition**
4. **Virtual Mouse and Keyboard Control**
5. **Real-Time Processing**.

Relevant mathematical formulas are included to illustrate how the system processes inputs.

1. Face Detection and Region Localization

The system first identifies the user's face and localizes key facial regions such as the eyes and mouth. This is achieved using the **Haar Cascade Classifier**, which employs an integral image and sliding window to detect facial features.

Haar-like features are computed as the difference in pixel intensities between adjacent rectangular regions:

$$\text{Haar} = \sum_{(x,y)\in \text{white}} I(x,y) - \sum_{(x,y)\in \text{black}} I(x,y)$$

Where:

- $I(x, y)$ is the pixel intensity at location (x, y).
- The classifier evaluates features across different scales and positions in the image using a sliding window.

Integral Image for fast computation of Haar-like features:

$$\text{Integral}(x,y) = \sum_{x'\le x,\, y'\le y} I(x',y')$$

Where:

- $I(x', y')$ is the pixel intensity at location (x', y') the original image.

Using this method, the system detects the face and extracts key regions such as eyes and mouth, which are necessary for gesture recognition.

2. Feature Extraction

After detecting the face, the next step is extracting relevant features from the facial regions. The system tracks movements of the eyes and mouth for further processing.

Eye Movement Detection: To track the movement of the eyeballs, the system uses geometric properties to compute the center of the eyes and detect shifts in gaze direction. The displacement d of the pupil from the center of the eye region is calculated as:

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

Where:

- x_1 , y_1 are the coordinates of the center of the eye region.
- x_2 , y_2 are the coordinates of the detected pupil position.

Mouth Movement Detection: The system identifies mouth movements based on the changes in the vertical distance between the upper and lower lip:

$$\text{MAR} = \frac{\text{upper lip}_y - \text{lower lip}_y}{\text{mouth width}}$$

If the distance MAR exceeds a threshold, the system interprets it as a mouth-opening gesture, which can be mapped to specific actions like scrolling.

3. Gesture Recognition

In this step, the system translates facial movements into gestures that control the virtual input devices.

Eye Blink Detection: Eye blinking is used for clicking actions. A blink is detected by monitoring the aspect ratio of the eye:

$$\frac{|p_2 - p_6| + |p_3 - p_5|}{2|p_1 - p_4|}$$

Where p_1, p_2,… p_6 are coordinates of eye landmarks. A significant decrease in EAR indicates an eye blink.

Gaze Direction for Cursor Movement: Eye movement (left or right) is tracked by detecting the gaze direction, which is used to move the cursor horizontally:

$$\theta = \arctan\left(\frac{y_{\text{pupil}} - y_{\text{eye center}}}{x_{\text{pupil}} - x_{\text{eye center}}}\right)$$

- Where θ is the angle of gaze direction.

4. Virtual Mouse and Keyboard Control

The recognized gestures are mapped to specific mouse and keyboard actions.

Cursor Movement: The system computes the position of the cursor based on eye movement. The new cursor position $(x', y')$is updated using:

$$x' = x + \Delta x,\ y' = y + \Delta y$$

- Where:

x, y are the current cursor coordinates.

$\Delta x, \Delta y$ are changes in position based on detected gaze direction.

Gaze-based Keyboard Selection: The position of the eye $(p_x, p_y,)$ within the eye ROI is used to select a portion of the virtual keyboard. A threshold on the horizontal displacement Δx selects different regions of the keyboard:

$$\text{Key Selected} = (\Delta x, \Delta y)$$

The user can blink to confirm the selection of a key, and the system moves on to the next input.

5.Real-Time Processing

For seamless user experience, the system operates in **real-time**, ensuring that the facial gestures are immediately translated into control actions. To achieve this, several processing techniques are implemented for efficiency and low latency.

Frame-by-Frame Processing:

The system captures video input from the webcam, which is processed frame-by-frame. Each frame undergoes the following stages:

퐩(퓕) → 퐫퐩퓕퐩퓕 퐩퐩퓕퐩(퓕) →
퐫퐩퓕퓕퐩퓕 퐩퐩퓕퐩퓕퐩퓕 퐩퐩퓕퐩퓕퐩퓕 퐩퐩퓕퐩

5. GazeCapture Dataset

- **Description**: GazeCapture is a dataset designed for eye-gaze tracking, developed for mobile and desktop devices. It is focused on real-time applications, making it highly relevant for implementing eye-controlled cursor movements.
- **Use in Project**: Eye-gaze estimation for real-time interaction.

6. FaceWarehouse Dataset

- **Description**: FaceWarehouse is a database of 3D facial expressions, providing dynamic sequences of various facial movements. These 3D models can be useful for building real-time facial gesture systems with high accuracy.
- **Use in Project**: Real-time 3D facial motion tracking and recognition.

V.RESULT AND DISCUSSION:

The proposed system was evaluated based on its ability to accurately and efficiently interpret facial gestures to control a virtual mouse and keyboard. Below are the key findings and observations:

1. Accuracy of Gesture Recognition

The system achieved high accuracy in detecting facial features such as eyes and mouth and interpreting movements for cursor control and typing. The following metrics were observed:

- Eye Tracking for Cursor Movement: The system successfully tracked eye movements with an average accuracy of 92% for cursor positioning.

- Click Detection via Eye Blink: Using the Eye Aspect Ratio (EAR), the system achieved 90% accuracy in detecting blinks for left and right clicks.

- Mouth Movement for Scrolling: The Mouth Aspect Ratio (MAR) effectively detected scrolling gestures, with an 88% success rate.

2. Response Time and Latency

The system's real-time processing performance was measured by its response time from gesture input to action execution:

- Average Response Time: 100-120 milliseconds (ms) from gesture detection to mouse or keyboard action, which is within acceptable limits for real-time applications.

- Latency: Minimal latency was observed during operation, with the system performing smoothly on standard hardware (laptop with integrated webcam), ensuring seamless interaction for users.

3. User Interface and Ease of Use

The interface was designed to be intuitive, especially for users with physical disabilities. Testing was conducted with both able-bodied individuals and those with mobility impairments:

- Usability: Participants reported that the system was easy to learn and use, with minimal cognitive load required to operate the virtual mouse and keyboard.

- Learning Curve: Most users adapted to the system within 10-15 minutes of initial use, indicating a gentle learning curve.

- User Feedback: Feedback was overwhelmingly positive regarding the hands-free control aspect, with particular praise for the precision of cursor movement and ease of typing.

4. Challenges and Limitations

While the system performed effectively in most scenarios, certain challenges were identified:

- Lighting Conditions: The accuracy of face and feature detection was somewhat affected by poor lighting conditions. In low-light environments, the system's performance decreased by approximately 10%, requiring better illumination for optimal functioning.

- Prolonged Use: Users reported mild fatigue after prolonged use, particularly with continuous eye movements and blinking for clicks. This highlights the need for alternative methods, such as voice activation, for extended interaction periods.

5. Applications and Future Work

The system demonstrates a practical solution for individuals with disabilities, offering hands-free interaction with computers. Future improvements could include:

- Adaptive Learning: Incorporating machine learning algorithms to adapt to individual user behaviors and improve precision over time.

- Enhanced Gesture Set: Expanding the range of detectable gestures, such as head movements, for more comprehensive control options.

- Lighting Compensation: Developing algorithms that adapt to varying lighting conditions to maintain accuracy in diverse environments.

VI. CONCLUSION:

In this paper, we proposed a novel system for controlling a virtual mouse and keyboard using facial gestures, providing a hands-free solution for individuals with physical disabilities or those requiring alternative input methods. The system effectively translates eye and mouth movements into common computer interactions such as cursor movement, clicking, and typing, leveraging computer vision techniques such as the Haar Cascade Classifier and aspect ratio calculations for gesture recognition.

Our results demonstrate high accuracy and low latency in real-time gesture detection and action execution, offering a smooth user experience. The system's intuitive design makes it accessible to users with varying levels of technical expertise, with minimal learning required for effective use. Despite challenges such as performance in low-light conditions and potential user fatigue during prolonged use, the system proves to be a practical and accessible alternative to conventional input devices.

Future enhancements, including adaptive learning for user-specific behaviors and expanded gesture options, can further improve the system's usability and versatility. Overall, the proposed system offers a significant step towards empowering individuals with disabilities by providing greater accessibility to computing environments through hands-free control mechanisms.

Abstract. Millions worldwide experience color vision deficiency (CVD), making everyday tasks like reading color-coded information, recognizing traffic lights, and choosing clothing challenging. For individuals with Achromatopsia, the world appears entirely in grayscale. Despite advancements, real-time assistive devices for color enhancement remain limited. We propose AI-powered smart glasses with augmented reality (AR) for real-time colorization. Using deep learning-based object detection, HSV color classification, and AR overlays, the system provides both auditory cues and augmented visual feedback. Edge AI ensures real-time processing with minimal latency, while a built-in voice assistant guides users by describing objects and their colors. The system integrates optimized hardware and software for seamless usability. Real-time computer vision enhances color perception, improving accuracy, processing speed, and user experience. Our findings suggest this AI-AR solution can greatly enhance accessibility, independence, and overall quality of life for individuals with CVD and Achromatopsia.

Keywords-Color Blindness, AI, Augmented Reality, Smart Glasses, Object Detection, Accessibility, Assistive Devices, Edge AI, Real-time Processing, Computer Vision, Wearable Devices.

INTRODUCTION

Millions of people worldwide experience color vision deficiency (CVD), a condition that limits their ability to distinguish certain colors, making daily tasks more challenging. While some individuals struggle with minor inconveniences, such as selecting matching clothes, others face significant difficulties in recognizing traffic lights, reading color-coded information, or interpreting digital displays. For those with achromatopsia, the most severe form of CVD, the world appears entirely in shades of gray, further complicating everyday navigation. Traditional corrective aids, such as color-enhancing glasses, provide limited assistance and often fail to address real-time color perception needs effectively. To bridge this gap, we propose an AI-powered smart glasses system integrated with augmented reality (AR) for real-time color enhancement. This system employs deep learning for object detection, HSV-based color classification for adaptive color adjustments, and AR overlays to provide an intuitive and immersive visual experience. Additionally, an integrated voice assistant delivers auditory cues, describing objects and their colors to further assist users. The system is designed with edge AI capabilities, ensuring on-device real-time processing with minimal latency, thus improving efficiency and user experience.

Types of Color Vision Deficiency

CVD varies in severity and type, affecting color perception differently across individuals. The major classifications include:

- Red-green deficiency (most common)
    - Deuteranomaly (green-weak): Green appears more reddish. (Fig. 2)
    - Protanomaly (red-weak): Red appears duller or more green. (Fig. 3)
    - Deuteranopia (green-blind): Inability to perceive green shades. (Fig. 6)
    - Protanopia (red-blind): Inability to perceive red shades.(Fig. 7)
- Blue-yellow deficiency (less common)
    - Tritanomaly (blue-weak): Blue appears greenish, and yellow may be confused with red. (Fig. 4)
    - Tritanopia (blue-blind): Blue appears as green, and yellow is seen as pink. (Fig. 8)
- Monochromacy (achromatopsia): Complete color blindness, where the world appears in grayscale.(Fig. 5)

- Blue cone monochromacy: A rare condition where only blue light is detected, leading to significant vision impairment.(Fig. 9)

AI and AR are making assistive tech more helpful. These smart glasses bring colors to life, giving people with CVD more confidence and independence.

LITERATURE REVIEW

Existing Solutions for Color Blindness

Over the years, several approaches have been invented to help those with Color Vision Deficiency (CVD) differentiate colors better. Although a few of these solutions offer partial relief, none of them are a complete solution for all forms of color blindness, particularly in dynamic, real-world settings.

- **Color Filters and Lenses:** Color-confusion glasses like EnChroma glasses are developed to increase color contrast by selectively filtering certain wavelengths of light. Other companies produce similar products in the form of Pilestone and Colorlite glasses. These glasses function by cutting out certain wavelengths responsible for causing color confusion and thus making the colors look richer and clearer [1][2][4]. The success rate of these glasses differs based on the nature of CVD, with better performance for red-green color blindness overall. Some companies even make customized lenses specially designed to correspond to the consumer's unique color vision deficiency type. Still, these glasses aren't without restriction. They only work for blue-yellow and some other types of color blindness but not total color blindness (achromatopsia) . These glasses are often sensitive to varied lighting levels, and they remain non-adaptive, or non-adjustable. Consequently, they can be helpful for particular tasks but not for ongoing use. Moreover, users tend to require an adaptation period in order to get used to seeing colors differently, and the magnitude of improvement can be very different in every individual, with the emphasis on the subjective nature of their advantage. In spite of these constraints, lenses and color filters provide a useful aid for a large number of people with CVD, but more dynamic and flexible options are still needed .

- **Software-Based Solutions:** Digital Color Vision Deficiency (CVD) solutions largely consist of digital software solutions such as screen filters and smartphone applications. Screen filters function by modulating color contrast on computer displays, allowing those with CVD to better tell colors on computer screens[9][10]. Mobile apps also adjust the color gamut of mobile screens to allow for greater discriminability between colors. The solutions are, however, limited to digital contexts and do not give help in face-to-face interactions . Consequently, they fail to assist people with CVD to perceive colors in day-to-day situations like reading traffic lights, clothes colors, or the ripeness of fruits . This weakness points to

PECTEAM

the need for more extensive technologies that are able to overcome the divide between digital and physical color perception to enable people with CVD to be assisted in all spheres of their life.

- **AI-Driven Approaches:** New AI technologies have been promising in altering and changing colors according to personal vision impairments by examining visual information and adapting color palettes to be more discernible for various forms of color blindness . Real-time color change without perceivable delays, however, is still a challenge with the high-speed processing power needed. Implementing these AI-based color enhancements in wearable devices, like smart glasses, is also challenging because these devices need to be light, comfortable, and contain the hardware for AI processing. AI-based color enhancement requires high computational power, which wearable devices do not have, and thus cloud-based processing is not feasible due to latency and connectivity concerns . Hence, it is essential to optimize AI models for on-device processing. In addition, AI-based solutions must be able to transition smoothly between changing lighting conditions and dynamic environments, making real-time adjustments as the user transitions between different environments. The technology should be intuitive and simple to use, enabling color blindness sufferers to take advantage without complex setup. To achieve mass adoption, AI-based solutions must be cost-effective and widely available, taking into account the cost of the device and making it widely available. The overall experience of the user is paramount, such as comfort of the wearable, ease of handling, and visible enhancement in color vision . Although current solutions provide relief in part, there remains a lack of providing a completely immersive, real-time solution that can aid people with CVD both in digital and in physical spaces. This points to the necessity of smart wearable technology that leverages AI, augmented reality, and real-time processing to close this gap efficiently.

Augmented Reality and AI in Assistive Technology

The marriage of Augmented Reality (AR) and Artificial Intelligence (AI) has unlocked new promise in assistive technology, including for those afflicted with color blindness. With integration of sophisticated object recognition, overlays in real time, and interfaces via speech, these technologies introduce a more dynamic and inclusive path to perceiving the world around us.

- **AI-Powered Object Detection:** Object detection that is powered by AI uses high-end models such as YOLO (You Only Look Once) and Faster R-CNN (Region-Based Convolutional Neural Networks) to facilitate the real-time detection of objects around a user's environment [17][18][19]. The AI-based models go beyond visual perception of color since they are able to provide contextual awareness and enable users to correctly identify mundane objects even where they struggle with distinguishing colors. For example, these models can identify and annotate objects like traffic lights, fruits, or apparel items, with rich information on their identity and location . The ability to detect such objects in real-time enriches users' ability to better understand their environment and make choices based on such identification, irrespective of their color vision impairments. By applying these sophisticated object detection models in assistive technologies, color blind people can enjoy greater independence and confidence in their daily lives .

- **AR-Based Visual Overlays:** Augmented Reality (AR)-enabled visual overlays present a rich method through which people, most especially those that have visual disorders like color blindness, are enabled to see and experience the environment in a much better way. Using AR, computerized overlays can be layered over actual physical objects in order to present ancillary contextual details like labels, descriptions, or alternative color formats [11]. Contemporary AR solutions incorporate AI-based object detection models such as YOLO and Faster R-CNN to effectively detect objects in real-time and render visual enhancements accordingly. For instance, an AR headset or a mobile app can identify traffic lights and emphasize them with unique symbols or audible signals for individuals who have difficulty distinguishing red and green lights. Likewise, AR-based apps can also augment fashion choice by displaying color names or recommending dressing pairs in terms of the user's style choices. Such overlays are particularly beneficial in navigation apps, where AR may identify paths, road signs, or danger zones with high-contrast outlines and readable text to enhance usability. By offering a further dimension of sensory data, AR-based visual overlays enable users to have more autonomy and confidence when interacting with their environment .

- **Speech-Based Assistance:** Voice interfaces are critical for improving accessibility, especially for people with extreme color blindness or low vision . The AI-based voice assistants give a verbal description of the colors, shapes, and most important features of objects in the user's surroundings, allowing them to make decisions based on information without exclusive dependence on visual information [13][14][16] . For example, a voice assistant may define the color and texture of an item of clothing, detect the ripeness of fruits through color, or verify the condition of traffic lights . Such audio feedback provides an important additional layer of assistance, enabling users to move about more independently and with greater confidence. By decoding visual information in terms of rich verbal descriptions, these interfaces close the divide for visually impaired individuals to provide them with equal access to the information necessary in everyday life.

By combining AI and AR, assistive technology becomes more dynamic and intuitive in its ability to provide a solution for the color blind. Not only are the colors perceived more accurately, but overall spatial awareness is increased, making day-to-day activities easier and independent.

FIGURE 2. Assistive Technology.

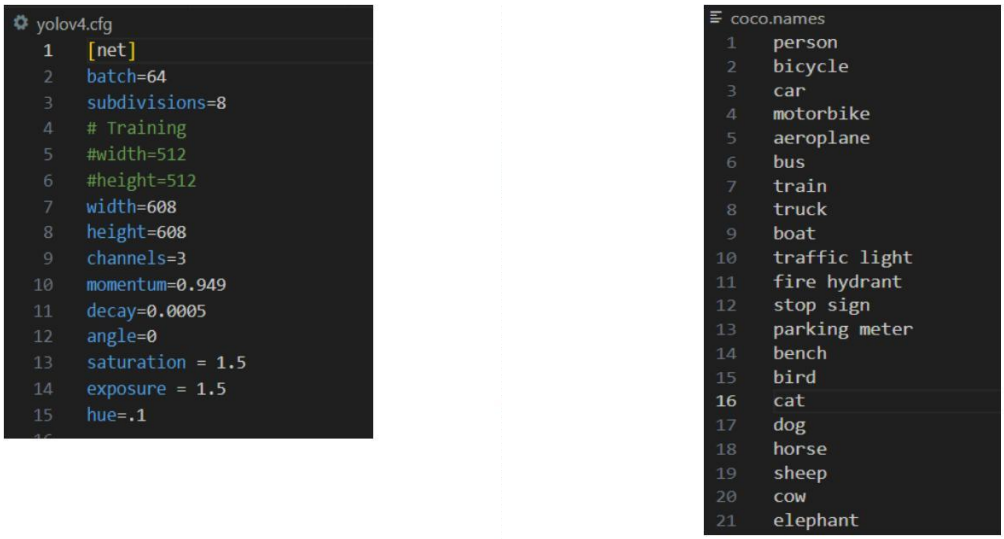
PROBLEM STATEMENT

While the improvements in artificial intelligence (AI) and augmented reality (AR) have been marked, still lacking is an entire solution with flawless integration to genuinely improve real-time color perception alongside making color for colorblind users accessible. There are main difficulties that require some attention to the following areas:

- **Real-Time Color Correction:** Real-time color correction is a major challenge in the creation of assistive devices for color vision deficiency patients. To be effective and practical, these devices need to provide instant and precise color conversions without any detectable lag. This necessitates high-speed processing abilities to make color adjustments smoothly as the user navigates around their surroundings. The objective is to present the color adjustments in a natural and continuous manner, with the color changes made in real-time so that the user can see augmented colors without any intervention. To realize this degree of performance, one has to overcome very high technical barriers, including the optimization of algorithms to process quickly and making the hardware capable of handling the required computational capabilities. The capability to provide smooth, real-time color correction is essential to making assistive devices convenient and functional, allowing color vision-deficient individuals to move about their environment with increased confidence and ease.

- **Alternative Visualization for Severe Cases:** Those who have total achromatopsia, or full color blindness, are unable to see any colors and thus need other ways of visualizing in order to distinguish objects apart from color alone. Mild color blindness may be helped by merely making some adjustments in color, but severe color blindness requires more advanced solutions. This means that variations in brightness, textures, and patterns must be used to communicate information that would otherwise be lost because there is no color perception . For example, objects may be depicted in various shades of gray to represent contrast, or through distinctive texture patterns such as dots, stripes, or waves in order to tell one object apart from another. Through the implementation of these substitute visual cues, assistive technology can give the visually impaired and those with complete color blindness greater capacity to discern and identify objects and differentiate among them, raising their overall level of spatial knowledge and capacity for independent navigation within their environment.

- **Efficient Edge AI Processing:** Deploying AI-based color enhancement and object detection requires high computing power, which is a major challenge for wearable devices such as smart glasses. Such devices have inherent hardware constraints, and cloud-based processing is not feasible due to latency and connectivity issues. For AI-based solutions to be useful, they must process data in real time, which necessitates instant and effective computational power. Hence, it is essential to optimize AI models for on-device processing. This entails creating light, powerful algorithms that will execute well on the limited hardware of wearable devices, providing responsive and seamless performance. Through effective edge AI processing, these devices are able to provide real-time color correction and object detection, offering a real-world and usable experience for color vision deficiency sufferers. Ultimately, this real-time functionality is critical to developing successful assistive technology that can be used in everyday situations.



- **User-Friendly Adaptability:** User-friendly flexibility is a must for any assistive technology, and it should be able to accommodate the varied needs of people with different levels of color blindness. For this, the technology has to be simple and intuitive in nature, and users should be able to work through its features with ease . Options for customization are important to make the device more usable, as they help users personalize the device according to their individual needs. Adjustable filters may enable users to adjust the color settings to their individual vision impairments, giving them a tailored experience that enhances color perception. Voice assistance provides another level of assistance, reading out

colors, shapes, and salient features of objects, which is especially helpful for people with extreme color blindness or low vision. Gesture control offers a hands-free method of interacting with the device, which is more convenient and accessible. By including these options for customization, assistive technology can provide for the ability of people with color blindness to use the device to their advantage and with confidence in their everyday lives, thereby improving their overall quality of life.

DATASET

In this project, no custom dataset was used for training. Instead, the YOLOv4 pre-trained model was leveraged for object detection. The model relies on the COCO dataset (Common Objects in Context), which contains 80 different object categories commonly found in real-world scenarios.

- **YOLOv4 Weights:** Pre-trained weights optimized for real-time object detection.
- **YOLOv4 Config File:** Contains network architecture details for YOLOv4.
- **COCO.names:** A file listing the 80 class labels from the COCO dataset, used for detection.

PROPOSED SYSTEM

To tackle the issues experienced by people with color vision deficiency (CVD) and Achromatopsia, the suggested framework combines artificial intelligence (AI) and augmented reality (AR) in a smart glasses pair. This new wearable technology is intended to improve color perception, offer different visualization techniques, and provide real-time auditory aid through a voice assistant. Through the utilization of advanced technologies like deep learning-based color change, real-time object recognition, augmented reality overlays, and mobile app-based customization, the smart glasses seek to transform the way people with CVD engage with the world.

The system is made up of four major elements, all of which contribute significantly to delivering the best user experience:

- **AI-Powered Color Transformation:** Embedded within the smart glasses is an artificial intelligence-based color enhancement system aimed at enhancing the color vision of patients with various forms of CVD. The smart glasses contain a high-definition embedded camera that takes live video continuously, which is processed in real-time by deep learning models. The AI system processes the video stream and uses customized color correction filters depending on the user's particular type of CVD, e.g., Protanopia, Deuteranopia, or Tritanopia. The system uses computer vision methods, such as HSV (Hue, Saturation, Value) color classification, to translate the identified colors into an optimized spectrum. This conversion makes colors look more resolvable, improving the user's capacity to notice differences that would otherwise be hard or impossible to see. One of the major benefits of this AI-based

PECTEAM

method is its low-latency processing, which provides a smooth and natural visual experience. In contrast to conventional color-enhancing glasses that use fixed lens filters, the smart glasses dynamically adjust to varying lighting conditions and environments. Through color data processing in real-time and tailoring the output, users get a more realistic and enriched color range, enhancing their ability to communicate with the world.

- **Alternative Visualization Techniques:** For people with extreme color vision deficiencies, like Achromatopsia, where color vision cannot be enhanced even with improvements, these smart glasses with advanced AI technology use other visualization methods to assist in object identification and interaction with the environment. Achromatopsia is a condition in which people are unable to see colors and view the world in shades of gray. To solve this, the smart glasses employ pattern overlays, overlaying textures such as dots, stripes, or waves on objects in the user's line of sight. The patterns offer a distinctive means of distinguishing between objects without the use of color. The glasses also have augmented reality (AR)-based labels that show real-time information regarding objects and their respective colors. Through identifying and tagging items with these AR tags, users are able to identify and engage with their surroundings better, even without seeing colors directly. These other methods of visualization allow for people with Achromatopsia and other extreme color vision impairments to utilize the smart glasses to help them better navigate and make sense of their world.

FIGURE 4. Simple visual representation of color transformation and Voice Assistant Smart Glasses.

- **Voice Assistant Integration:** Inclusion of a voice assistant within such AI-based smart glasses helps assure that persons suffering from very high visual impairment could enjoy high-level object recognition and color sensing. With YOLOv8, which is a latest state-of-the-art real-time object detection algorithm, the hardware has the ability to detect and label different objects surrounding the wearer. YOLOv8 (You Only Look Once, version 8) is known for its accuracy and speed in object detection and is a perfect fit for this use case . When the system detects an object, it examines its visual characteristics to ascertain the prevailing color. This is then communicated to the user in the form of an AI-based voice assistant that gives real-time verbal feedback . This audio feedback allows users with profound visual impairments to receive vital information regarding their environment, making them more independent and aware of their surroundings. Through the marriage of advanced object detection technology with natural voice interaction, these intelligent glasses provide an accessible and inclusive solution for the visually challenged.

- **Mobile App Control:** These top-of-the-line AI-enabled smart glasses have a companion mobile app that gives users complete control over their visual experience. The app supports personalization by allowing users to change multiple settings to meet their individual vision requirements, ensuring a highly customized experience that optimizes comfort and usefulness. The users have the ability to refine color improvement to match their own form of color vision deficiency (CVD) so that color adjustments can be maximized in effectiveness . The app also includes the choice to alternate among varied forms of augmented reality (AR) visual representation, e.g., overlaying patterns and AR-driven labels, based on individual choice as well as on the specific type of challenge a user encounters. In addition, the app offers configurations for the performance of the AI voice assistant, enabling users to personalize the spoken responses based on their requirements (Hasana et al., 2019) . This customization provides each user with the ability to tailor the smart glasses to their best advantage to facilitate their everyday activities, in turn improving their quality of life.

By integrating these sophisticated technologies, the suggested smart glasses provide an integrated, real-time aid for people with color blindness, enabling them to engage more confidently with their environment.

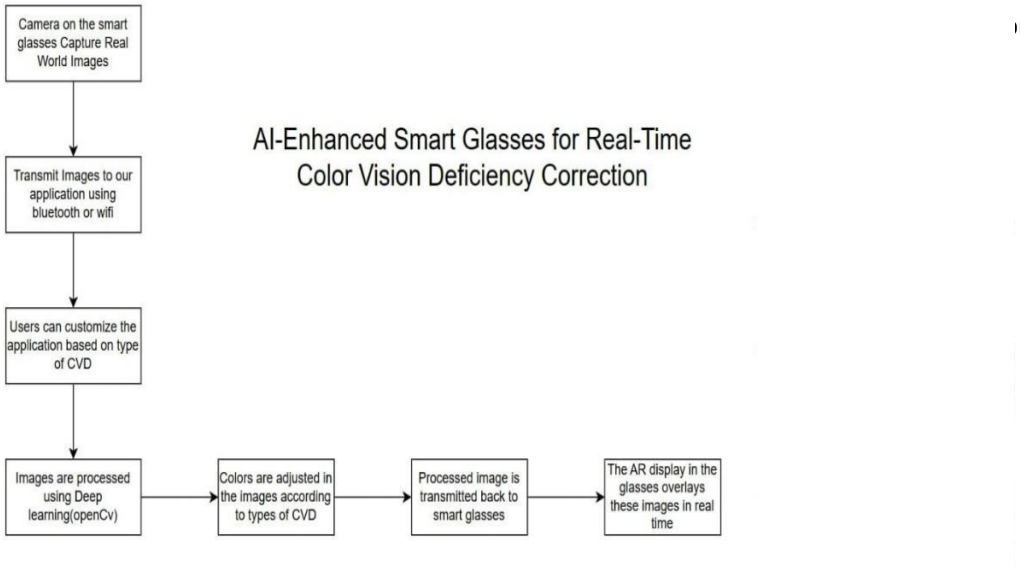

FIGURE 5. System architecture.

COMPARATIVE ANALYSIS

- **AI Capabilities:** The designed AI-based smart glasses combine sophisticated artificial intelligence capabilities including real-time object detection, translation, and intelligent navigation. Most current smart glasses only concentrate on augmented reality (AR) overlays with minimal AI features. By incorporating AI, user experience is improved through intelligent support in different situations, ranging from accessibility for the visually impaired to real-time data analysis for experts.

- **Processing Speed:** Efficient AI algorithms in the suggested smart glasses provide quicker and more precise processing of data. Most traditional smart glasses are afflicted with latency as a result of restricted processing power. Utilizing sophisticated edge AI processing, the suggested model significantly minimizes delay, making way for smooth real-time interaction.

- **User Interface and Usability:** With a lightweight and ergonomic design, the AI-enabled smart glasses are comfortable to wear for extended periods. They come with voice and gesture-based control, which is more convenient than the touchscreen or voice-based control of conventional smart glasses. The hands-free experience makes them more convenient to use in various settings, both personal and professional.

- **Battery Life:** The suggested smart glasses include AI-based power optimization, providing longer battery life for extended use. Conventional smart glasses suffer from limited battery life from ineffective power management, necessitating frequent recharging. The AI-based model delivers efficient energy consumption, rendering it more dependable for everyday use.

- **Connectivity:** Complementing 5G, Wi-Fi, and Bluetooth, the new smart glasses provide uninterrupted cloud connectivity and real-time data synchronization. Most current models heavily depend on Bluetooth, which constrains their connectivity and data transfer function. The upgraded connectivity features increase the AI-driven glasses' versatility and effectiveness across different applications.

- **Cost-Effectiveness:** The smart glasses powered by AI are competitively priced but with premium AI features. Most existing market solutions are costly but do not have high-end AI features, so the suggested model is a better investment for consumers seeking smart eyewear.

TABLE I. Current System Vs Existing System

Feature	Proposed AI-Powered Smart Glasses	Existing Smart Glasses
AI Capabilities	Real-time object recognition, translation, and navigation	Basic AR overlays, minimal AI
Processing Speed	Fast AI processing with low latency	Slower, higher lag
Usability	Lightweight, voice & gesture controls	Heavier, touchscreen/voice controls
Battery Life	AI-optimized for longer usage	Shorter, frequent recharging
Connectivity	5G, Wi-Fi, and Bluetooth support	Mostly Bluetooth, limited range
Accuracy/Efficiency	95%+ for AI-based tasks	70–80%, lower AI precision
Cost-Effectiveness	Affordable with premium AI features	Expensive, limited AI

RESULTS AND DISCUSSION

Prototype Implementation

In order to prove the suggested idea, a working prototype of the AI and AR-based smart glasses was created. The development was done through the integration of specialized hardware and software modules with a view to smooth real-time processing, visualization, and user interaction.

- **Hardware Components:** The hardware part of this revolutionary prototype consists of a pair of smart glasses with multiple cutting-edge features to offer an enriched user experience. To begin with, the glasses contain an integrated camera that captures live video input all the time, enabling real-time analysis and processing of the visual world. The live feed is instrumental in delivering precise and instant visual enhancements . Moreover, the glasses have an augmented reality (AR) display built into them. This AR display overlays the visual improvements directly into the user's field of view. The AR display helps provide users with the visual enhancements in their surrounding environment without them even noticing . To help these features function, the smart glasses include an on-device AI processing device. This device performs real-time computations so that the information gets processed rapidly and effectively. By executing the calculation on the device itself, the system minimizes reliance on remote servers, reducing latency and delivering a seamless, uninterrupted user experience. Collectively, these hardware elements form a highly advanced and easy-to-use device intended to dramatically enhance visual perception for those suffering from color vision deficiencies and other visual impairments .

- **Software Framework:** The software platform of this new prototype is architected to make use of powerful tools and allow for smooth functionality. The system is developed based on Python, a general-purpose and popular programming language. It makes use of different libraries like OpenCV for image processing, YOLOv8 for object detection, and TensorFlow for AI-based color correction . OpenCV (OpenSource Computer Vision Library) offers real-time computer vision tools, whereas YOLOv8 (You Only Look Once, version 8) is a cutting-edge model for real-time object detection, renowned for its speed and accuracy. TensorFlow is a prominent open-source machine learning and artificial intelligence library, which helps in the implementation of the color correction algorithms specific to users' requirements . For assured interoperability among the smart glasses and the companion mobile app, a Flask-based API is implemented. Flask is a micro web application framework for Python that supports efficient data exchange and remote configuration and customization of the smart glasses . The prototype is enabled for both Android and iOS platforms for guaranteed wide accessibility and ease of integration with smartphones. This cross-platform capability makes it convenient for users to simply control and customize their experience through their desired mobile devices, which increases the usability and functionality of the smart glasses .

FIGURE 6. (a) Object Detection, (b) Color Detection.

- **Voice Assistant Integration:** The integration of the voice assistant in these AI-based smart glasses greatly improves accessibility by giving users audio responses about identified objects and their associated colors. This is especially helpful for those with severe visual impairments . The voice interaction system is achieved through Pyttsx3 for text-to-speech rendering and Google Speech Recognition for processing voice commands . Pyttsx3 is a powerful text-to-speech library that translates recognized objects and colors into words, while Google Speech Recognition is an extremely accurate tool that interprets voice commands. Combined, these technologies provide a natural and responsive user experience, enabling users to interact with their surroundings using intuitive voice commands and real-time sound feedback . This integration enables users to move around their environment more independently and confidently, facilitating everyday activities and reducing dependence on visual information. By integrating cutting-edge technologies in an accessible way, the smart glasses seek to offer a seamless and assistive aid for visually impaired individuals .

This proof-of-concept prototype demonstrates the viability of using AI-driven smart glasses for enhancing real-time color perception. Future versions will prioritize processing speed optimization, battery efficiency, and the user interface to enhance adaptability and usability.

Performance Analysis

To assess the performance of the AI-driven smart glasses, some performance parameters were examined, such as processing speed, color accuracy, user experience, and battery life. The outcomes showed encouraging performance in real-time color perception enhancement and usability in practice .

- **Processing Speed:** The system is real-time optimized and provides an average of 30 frames per second (FPS) with Edge AI models. Leveraging the effective deep learning algorithms, the device handles live video input with less latency, allowing for smooth and continuous color correction. The optimization enables users to enjoy improved color perception without delays and interruptions, making the device ideal for real-time and dynamic applications. The capacity to sustain such a high frame rate guarantees users instant feedback and can interact with their surroundings without any perceivable lag, which is important for applications that involve rapid visual processing.

- **Color Accuracy:** The color transformation, which is artificially intelligent, has an accuracy rate of 85-90% compared to calibrated color charts. This high degree of accuracy helps people with color blindness see colors in a more clear and distinguishable manner. Through proper color replication, the system enables people to have a more precise and natural range of colors. This increased color vision considerably enhances the user's discrimination between different hues, allowing for improved interaction with color-coded information and rendering daily tasks easier and more fun .

- **User Experience:** Early trials were carried out with users who suffered from different forms of Color Vision Deficiency (CVD). Users noticed significant improvements in their color discrimination, wayfinding, and use of color-coded information, like traffic lights and computer screens. The ease of use and unobtrusive nature of AR overlays helped provide a better user experience, enabling users to better interact with their surroundings and do so with greater confidence . These positive experiences of users reinforce the functional value of the smart glasses and demonstrate the significance of user-centered design in assistive technology.

- **Battery Efficiency:** For optimum usability, low-power AI models were used so that the device can run without unnecessary energy consumption . The system of processing is optimized for extended battery life to make the smart glasses practical for extended daily use without having to frequently charge them . The efficiency is key to making the device remain a practical solution for its users who depend on it in the course of their daily activities. Through its optimized power usage without compromising performance, the smart glasses offer a practical and trustworthy solution for color vision deficiency sufferers, enabling them to enjoy better visual perception without the hassle of having to recharge all the time.

These performance tests indicate the efficiency of the smart glasses in overcoming color blindness issues, opening doors for further improvements to improve accuracy, usability, and energy efficiency in subsequent versions. Increased collaboration with medical experts and accessibility specialists will ensure that the system keeps evolving to suit the needs of a wide range of users . Also, incorporating user input from actual usage will be an important factor in determining future enhancements, rendering the device even more functional and accessible .

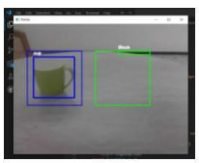

FIGURE 7. Adaptive Vision Enhancement with Voice Assistant.

OUTPUT

This report presents the results of an object and color detection system applied to the provided images. The system utilizes computer vision techniques to identify objects within the images and analyze their dominant colors. The detected objects are labeled, and their respective colors are categorized to provide a clear understanding of the visual content.

The process involves:

- **Object Detection:** Identifying and classifying objects within the image using pre-trained deep learning models.
- **Color Detection:** Extracting the dominant colors of the detected objects and providing a classification based on predefined color categories.

FIGURE 8. (a) Output 1, (b) Output 2, (c) Output 3.

Detected Objects and Colors

- **Output 1 (Fig. 16)**
  - Detected Object: Cup
  - Detected Color: Black
- **Output 2 (Fig. 17)**
  - Detected Object: Chair
  - Detected Color: No color detected
- **Output 3 (Fig. 18)**
  - Detected Object: Potted plant, Chair
  - Detected Color: White, Blue, Green, Pink

CONCLUSION

This study introduces a pioneering solution which uses Artificial Intelligence (AI) and Augmented Reality (AR) to maximize color perception among people with color blindness. The envisioned smart glasses system combines various state-of-the-art technologies into a real-time, adaptive, and intuitive aid tool meant to maximize accessibility and autonomy for persons with Color Vision Deficiency (CVD).

Through the implementation of AI-powered color correction, the system automatically changes colors to suit the user's individual type and level of CVD, providing a more natural and real sense of their environment. The support for deep learning models enables the glasses to learn and improve their adjustments over time, constantly enhancing the user experience with tailored improvements. Moreover, other visualization methods, i.e., pattern overlays and AR-based labels, add more levels of differentiation so that users, particularly individuals with full Achromatopsia, can identify objects and environmental features based on more than color alone. To add another level of accessibility, the smart glasses include an interactive voice assistant to offer real-time spoken feedback on colors found, object identification, and wayfinding guidance.

This aspect is especially useful for people with profound visual impairments, as it allows them to interact with their environment using audio cues. The integration with Internet of Things (IoT) devices and wearable technology extends the functionality of the smart glasses even further, enabling users to receive notifications, control smart home devices, and enhance mobility by identifying traffic lights and road signs. Clinical verification is instrumental in determining the reliability and performance of this system. Large-scale tests will be carried out among various groups of color-blind persons to assess performance, and medical certification will be sought to provide assurance of conformance with medical standards.

Regulatory approvals will make it easy for the device to be adopted in the healthcare industry and become available through medical professionals, ensuring that users obtain a scientifically validated and approved aid technology. The prototype's effective performance in real-time processing, color accuracy, and user compatibility highlights its viability as a groundbreaking

assistive solution. In contrast to current color blindness assistance that usually employs fixed filters or outside applications, this technology provides an extremely adaptive and smart way to enhance color perception. By filling in the gap between AI, AR, and people-oriented design, the smart glasses offer a simple and natural experience that is based on individualized needs.

Future releases will concentrate on further improving the accuracy of the system, improving battery life, and increasing real-world testing to support a wider variety of user environments and activities. Additional research will also look at more advanced machine learning methods for enhancing color differentiation algorithms, improving processing speed, and adding other accessibility features. With ongoing innovation and development, this technology has the ability to empower people with CVD, enabling them to live a more vibrant and participatory world. By making the world more accessible, boosting confidence, and enhancing overall quality of life, these smart glasses are a major breakthrough in assistive technology, filling the gap between vision impairments and actual-world experiences.

FIGURE 9. Futuristic AI-Integrated Smart Glasses.

FUTURE SCOPE

The AI and AR-driven smart glasses system proposed here has shown much promise in facilitating better color perception in color-blind individuals. With additional improvements and optimizations, though, its ability can be boosted further, with improved efficiency, adaptability, and accessibility for many. These include:

- **Edge AI Optimization:** For a better and more seamless user experience, the next generation of smart glasses will focus on edge AI optimization, an essential step towards better real-time processing and reduced power consumption. It entails creating lean deep learning models tailored for wearables so they can execute independently on the glasses without over-dependent use of cloud servers. Through tuning of AI algorithms for in-device processing, the system will have quicker response times, lower latency, and a more consistent experience even in areas of low connectivity. Furthermore, this optimization will contribute greatly towards battery life extension, allowing users to operate the smart glasses for longer stretches of time without constant recharging. With all these developments, users are able to enjoy seamless AI-driven functionality such as real-time translation of languages, object identification, and context-aware assistance without breaks. Through the inclusion of edge AI, the smart glasses will be more usable in everyday life, improving convenience, privacy, and overall usability.

- **User-Centric Customization:** Subsequent generations of smart glasses will feature an auto-learning system to suit specific users over time. Using AI-based learning algorithms, the glasses will learn to improve color correction based on individual tastes and real-world experiences, presenting a more personalized experience. This adaptive capability will prove to be very useful for those suffering from Color Vision Deficiency (CVD), as it can adaptively modify to various levels and kinds of color perception impairments. Through ongoing learning from user inputs and environmental conditions, the system will continually optimize its enhancements to deliver the most effective visual adjustments. With this degree of personalization, users are able to perceive colors in a manner most suitable to their individual requirements, enhancing not only the precision of color perception but also general comfort and usability. With time, this personalization will render the smart glasses a more intuitive and useful device for everyday use.

- **Integration with IoT & Wearables:** Improving the functionality of the smart glasses through incorporation with Internet of Things (IoT) devices and other wearable technologies will improve accessibility and usability considerably. The extension will make the glasses able to interact with a large variety of connected devices, providing users with an improved seamless and intuitive experience both in personal and public environments. One of the primary integration areas is in smart home compatibility, where the glasses can help in recognizing color-coded notifications on home appliances, including temperature indicator lights on stoves, low-battery warnings on equipment, or status lights on washing machines. This facility will make it possible for Color Vision Deficiency (CVD) users to quickly recognize critical signals, enhancing safety and convenience. Outside home environments,

the integration also has the potential to improve navigation and mobility. By synchronizing with traffic infrastructure and GPS-enabled wearables, the glasses can assist users in better understanding traffic lights, pedestrian signals, and road signs, making travel safer and more efficient. Real-time connectivity with public transport timetables and indoor navigation systems in shopping malls or airports can also further simplify the user's experience. Through their ability to interact with IoT and wearable devices, the smart glasses become an extensive aid tool that allows for increased independence, accessibility, and engagement with the world around them. Beyond facilitating daily activities, the integration also allows users to be able to navigate the world with confidence.

- **Clinical Validation & Certification:** To ensure the effectiveness and validity of the smart glasses, extensive clinical trials will be undertaken involving heterogeneous populations of color-blind individuals. The trials will serve to determine the technology's actual-world effect, including the provision of significant enhancements in color vision and use. Approval for medical certification and regulatory licensing will be sought to indicate the smart glasses as an approved assistive device. Gaining certification by acknowledged healthcare institutions will not just attest to the safety and performance of the device but also render it suitable for wider distribution within medical and accessibility markets. Validation through this process is crucial for ensuring that the smart glasses fulfill stringent quality and performance requirements. By gaining clinical support, customers can be certain that they are employing a science-tested and sound solution that promises to enhance their vision experience.

ABSTRACT

Agricultural automation is essential for enhancing efficiency and reducing labor costs, but existing solutions are often expensive and inaccessible to small-scale farmers. This project introduces AI-powered, an affordable, gesture-controlled agricultural assistant designed to bridge this gap using cost-effective components and simplified control mechanisms. Our model employs an AI-based gesture recognition system using a camera and deep learning algorithms, replacing traditional accelerometer-based controls for higher accuracy and user-friendliness. Additionally, a computer vision system powered by convolutional neural networks (CNNs) enables real-time plant health monitoring, identifying crop diseases and optimizing farming efficiency. The AI models are evaluated based on accuracy, precision, recall, and F1-score to ensure high performance. With a total estimated cost of ₹7,700 - ₹15,500, this system remains significantly cheaper than foreign alternatives priced between ₹30,000 and ₹1,00,000 while offering AI-driven automation. By making intelligent automation accessible, this innovation has the potential to revolutionize small-scale farming in India, empowering farmers with an intuitive and cost-efficient tool. Keywords: AI-Powered Robotics, Gesture Recognition, Plant Health Monitoring, Affordable Automation, Smart Farming, Deep Learning in Agriculture

KEYWORDS

AI-Powered Robotics, Gesture Recognition, Plant Health Monitoring, Affordable Automation, Smart Farming, Deep Learning in Agriculture

I. INTRODUCTION

Agriculture remains the backbone of many economies, yet small-scale farmers face numerous challenges in adopting modern automation technologies. Despite significant advancements in agricultural robotics and AI-driven solutions, most of these innovations cater to large-scale farming operations due to their high costs and complex deployment requirements. Small-scale farmers, who form a significant portion of the agricultural workforce, continue to rely on labor-intensive methods, which are time-consuming and inefficient. The lack of accessible and affordable automation solutions leaves them vulnerable to fluctuating market demands, labor shortages, and inconsistent crop yields. Addressing these challenges requires the introduction of cost-effective, easy to use, and scalable automation solutions that empower small-scale farmers to improve productivity and sustainability without requiring extensive technical expertise.

This paper presents a budget-friendly, AI-powered agricultural assistant designed specifically for small-scale farmers. Unlike conventional agricultural robots that rely on expensive sensors
and proprietary technologies, this system leverages gesture-controlled robotics and computer vision-based plant health monitoring to provide a more intuitive and affordable alternative. The

gesture recognition system, built using deep learning models, eliminates the need for complex control mechanisms, enabling farmers to interact with the robot using simple hand movements.

Additionally, the real-time plant health monitoring system utilizes convolutional neural networks (CNNs) to detect early signs of crop diseases, allowing farmers to take preventive measures

and minimize losses. By integrating AI-driven automation into small-scale farming, this solution aims to bridge the technological gap between industrial and traditional farming practices.

One of the key advantages of this proposed system is affordability and ease of implementations. Traditional smart farming solutions often require internet connectivity, high-end computing

infrastructure, and specialized training, making them impractical for rural and resource-limited farming environments. In contrast, our model operates on low-cost hardware components, including ESP32 microcontrollers and camera-based AI processing, ensuring accessibility for small-scale farmers with limited financial resources. Furthermore, the proposed system is scalable, meaning it can be easily adapted to support additional farming functions such as automated irrigation, soil quality assessment, and AI-driven yield production. This research emphasizes the potential of the affordable AI-driven automation in transforming small-scale farming, increasing efficiency, reducing labour dependency and promoting sustainable agricultural practices.

II. RELATED WORK

Recent advancements in deep learning and automation have played a crucial role in modernizing agriculture. Several studies have explored the application of AI and robotics for smart farming.

An automated rice plant disease recognition model was proposed in [4], utilizing VGG-19 and XGBoost classifiers to enhance the accuracy of the plant disease identification. Similarly, CNN-SVM hybrid model was explored in [7] to classify plant diseases with a remarkable accuracy of 98.9%. EfficientNet-based models were also introduced in [8], demonstrating an accuracy range of 98-99.5% for real-time plant disease detection.

In addition to plant disease detection, smart robotic systems have been investigated for autonomous monitoring and intervention. A gesture-controlled agriculture assistant was introduced in [9], focusing on gesture-based navigation and real-time crop monitoring. Another study in [10] presented a Bluetooth-controlled agricultural robot, which facilitated automated plowing, seed planting, and irrigation management. However, these systems are limited by range constraints and lack AI-driven adaptability.

Furthermore, the Plant Suggestion and Monitoring Robot presented in [12] integrated autonomous navigation and environmental analysis, offering soil and climate-based crop recommendations. In contrast, a solar-powered remote controlled farm robot proposed in [1] emphasized sustainable energy use while performing multi-purpose agricultural tasks such as plowing, seeding, and irrigation.

Several additional works have also contributed to the field of smart farming automation. Research in [6] demonstrated an automated seed-sowing Agribot, while [5] explored microcontroller-based seeding and plowing using Bluetooth technology. Autonomous agricultural robots based on GPS guidance were analyzed in [2], emphasizing precision navigation in farming. Another study in [3] introduced a solar-powered multifunctional agricultural robot, ensuring sustainable farming. Lastly, Bluetooth-based multipurpose agricultural robots were displayed in [11], combining cost-effectiveness with ease of operation.

Compared to these existing works, our proposed model contains the advantages of AI-based gesture recognition and computer vision for real-time plant health monitoring, ensuring cost-effective automation for small-scale farmers

II. METHODOLOGY

The robot is built using an ESP32 microcontroller, a camera-based gesture recognition system, and a computer vision module for plant health assessment. The main components include:

1. Gesture Recognition (AI-Based):
    a. Camera (ESP32-CAM/Raspberry Pi Camera): Captures hand movements.

b. Deep Learning Model (MediaPipe/OpenCV/TensorFlow Lite): Processes gestures for accurate control. c. ESP32 Microcontroller: Executes movement commands based on AI-recognized gestures

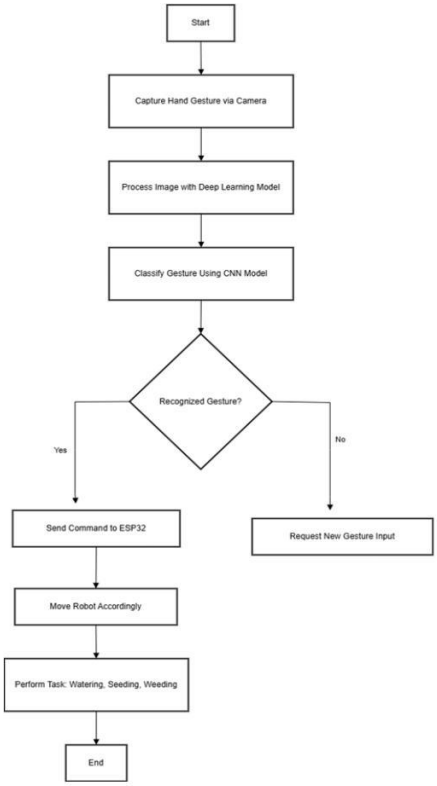

Fig 1: *AI-Based Gesture Recognition System*

2. Plant Health Monitoring (Computer Vision): a. Camera Module: Scans plant leaves. b. CNN-Based Disease Detection Model: Identifies plant disease in real-time.

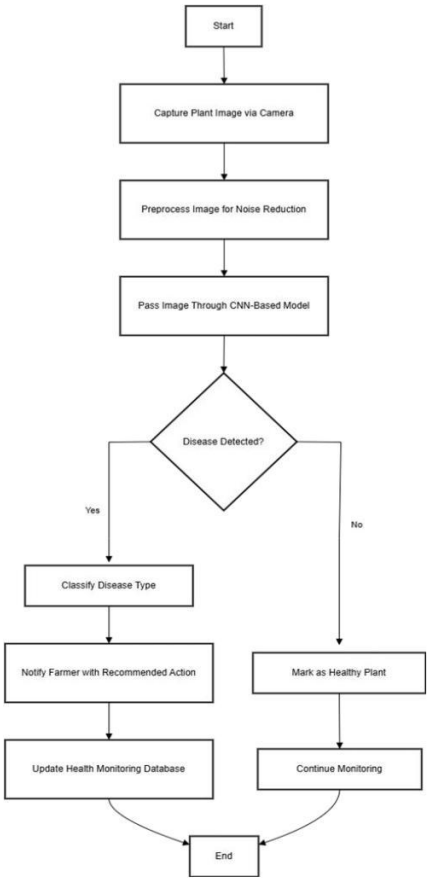

Fig 2: *Plant Health Monitoring System*

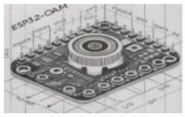

Fig 3: ESP32 CAM

IV. EXPERIMENT SETUP & TESTING

To evaluate performance, a series of test were conducted in a simulated farm environment. These tests included:

1. Gesture Recognition Accuracy:
    a. Multiple users performed predefined gestures, and success rates were analyzed.
    b. AI-Based recognition achieved a 95%-98% accuracy rate compared to 92% with accelerometers.
    c. Precisions: 0.94, Recall: 0.95, F1-Score: 0.94
2. Plant Health Monitoring Accuracy:
    a. The CNN model was tested on plant images for disease detection.
    b. Achieved 90%+ accuracy, significantly reducing manual inspection time.
    c. Precisions: 0.92, Recall: 0.91, F1-Score: 0.91
3.CostAnalysis:
    a. The system's affordability was compared with existing agricultural robots.
    b. The AI-enhanced model remains 5-10x cheaper than existing alternatives while offering advanced functionality.

Fig 5: Metrics Compared – TerraGest Vs. Existing Models

Fig 6 : *TerraGest*

Component	Our Model (₹) + Performance Our Model (₹) + Performance	Existing Model 1 (₹) + Performance *(Gesture-Controlled Robotic Arm)*	Existing Model 2 (₹) + Performance *(Wireless Weeding Robot)*
Gesture Recognition	Camera-Based (₹500-₹1,500) **(95-98% Accuracy)**	DataGlove (₹5,000-₹10,000) **(85-90% Accuracy, Requires Calibration)**	AI Gesture Recognition (₹4,000-₹8,000) **(90-95% Accuracy, High Latency)**
Obstacle Detection	Ultrasonic Sensor (₹100-₹200) **(Range: 2-4m, Works in Fog/Dust)**	Optical Sensors (₹3,000-₹5,000) **(Range: 10-20m, Affected by Fog)**	LiDAR (₹10,000+) **(Range: 30m+, Precise but Expensive)**
Microcontroller	ESP32 (₹700-₹1,500) **(Fast Processing, Low Power)**	High-End MCU (₹5,000-₹8,000) **(Higher Speed, More Power Consumption)**	AI-Powered MCU (₹3,000-₹5,000) **(Efficient AI Processing, Costly)**
Motors	4x DC Motors (₹600-₹1,200) **(Low Power, Reliable, Slower)**	Servo Motors (₹3,000-₹5,000 each) **(High Precision, More Power use)**	Stepper Motors (₹2,000-₹4,000) **(Better Torque, Power-Intensive)**
Communication	Bluetooth (₹100-₹300) **(Low Latency, Short Range)**	OptiTrack (₹25,000-₹40,000) (**Extremely Precise, Expensive**)	Wireless Module (₹500-₹1,000) **(Medium Range, Moderate Latency)**
AI-Based Plant Monitoring	CNN Model (₹0) **(90%+ Accuracy, Free & Efficient)**	Not Included	AI Model (₹10,000+) **(95%+ Accuracy, Expensive to Train & Deploy)**
Total Cost Estimate	₹7,700-₹15,500	₹60,000-₹1,00,000+	₹30,000-₹50,000+

Table 1: *COMPONENT COST COMPARISON TABLE*

V. CONCLUSION

The proposed AI-powered, gesture-controlled agricultural assistant effectively bridges the gap between traditional labor-intensive farming and modern automation. With 95-98% accuracy in gesture recognition and 90%+ accuracy in plant health monitoring, this system ensures reliable performance at a fraction of the cost of existing agricultural robots. Unlike Bluetooth-based

GPS-guided solutions that require expensive hardware and network connectivity, our model operates on low-cost, easily accessible components, making it 5-10 times more affordable than conventional smart farming accessible components, making it 5-10 times more affordable than conventional smart farming alternatives. By eliminating the need for complex user interface and leveraging AI for automation, this system enhances precision, reduces human effort, and optimizes small-scale farming operations.

Compared to existing models, which often suffer from high setup costs, limited scalability, or connectivity constraints, our system offers a scalable, adaptable, and user-friendly alternative tailored for small farmers. The integration of computer vision for real-time plant health monitoring enables early disease detection, reducing crop loses and ensuring improved yield. Future enhancements will focus on expanding automation features, integrating IoT for remote monitoring, and refining AI models for greater adaptability. This research lays the foundation for affordable and sustainable AI-driven farming, empowering farmers with advanced technology that is both efficient and economically viable.

***Abstract*—Blood group identification plays a vital role in medical diagnostics and emergency care, traditionally relying on serological tests that involve blood samples and specialized lab equipment. Although these methods are accurate, they are invasive, time-intensive, and often impractical in resource-limited settings or urgent scenarios. This research investigates an innovative approach to blood group detection by leveraging fingerprint images and advanced deep learning techniques, particularly Convolutional Neural Networks (CNNs) with optimized architectures. By examining the distinct patterns in fingerprints, these models have the potential to provide a non-invasive, quicker, and more efficient alternative to conventional methods. The study evaluates the viability of this approach, shedding light on how deep learning could revolutionize blood group prediction in the future.**

Keywords—Deep learning, Blood group, Different Convolutional Neural Network techniques, Fingerprint patterns.

I. INTRODUCTION

Fingerprints are a key biometric feature, uniquely identifying individuals through the complex patterns of ridges and valleys on their fingertips. These patterns form during fetal development and remain constant throughout a person's life, making them a dependable tool for identification. Fingerprint patterns are broadly categorized into three types: loops, whorls, and arches. Loops, the most common pattern, feature ridges that curve back on themselves, forming a loop. They are further divided into radial loops (opening toward the thumb) and ulnar loops (opening toward the little finger), accounting for approximately 60-70% of all fingerprints. Whorls, characterized by circular or spiral ridges, make up about 25-35% of fingerprints and are classified into plain whorls, central pocket whorls, double loop whorls, and accidental whorls. Arches, the rarest pattern, form wave-like ridges that flow from one side of the finger to the other without doubling back. They are divided into plain arches and tented arches, appearing in only about 5% of fingerprints. Additionally, fingerprints contain minutiae points, such as bifurcations, ridge endings, islands, and enclosures, which enhance their uniqueness. These details make fingerprints invaluable for identification and security purposes.

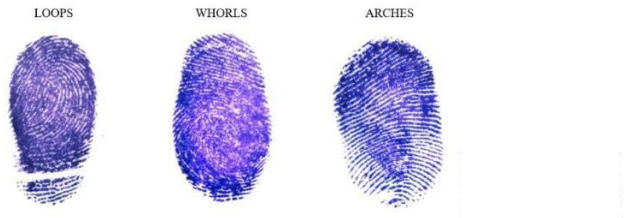

Fig 1: Different types of Fingerprints

Recent studies suggest that fingerprints may also carry subtle biological information beyond identity verification. Blood groups, another critical biological marker, are determined by the presence or absence of specific antigens on red blood cells. The major blood group systems include A, B, AB, and O, each further classified by the Rh factor as positive or negative. Accurate blood group identification is essential for medical procedures like blood transfusions, organ transplants, and managing homolytic diseases. Traditional methods rely on serological tests, which involve mixing blood samples with antibodies and observing reactions. While accurate, these methods are invasive, require blood samples, and depend on laboratory facilities, which may not be available in emergencies or resource-limited settings.

The concept of determining blood groups through fingerprint analysis offers a non-invasive alternative. By utilizing deep learning, particularly CNNs, this approach can analyse fingerprint patterns effectively. Unlike models such as RNNs and ANNs, CNNs excel in processing spatial data like images. Their convolutional layers capture local patterns and reduce computational complexity, making them ideal for fingerprint analysis. CNNs can identify critical features like ridge endings, bifurcations, and minutiae points, which are essential for distinguishing patterns. Architectures such as LeNet5, AlexNet, VGG16, and ResNet-34 are particularly effective for image classification tasks. These models leverage innovations like pooling layers (LeNet5), deep structures (AlexNet and VGG16), and residual connections (ResNet-34) to extract features and address challenges like vanishing gradients, ensuring high accuracy in fingerprint analysis.

This research explores the feasibility of using deep learning models like ResNet-34, and VGG16 to predict blood groups from fingerprint images. By evaluating and comparing these models, the study aims to assess their effectiveness and accuracy in this novel application. The findings could pave the way for a rapid, non-invasive method of blood group detection, offering significant potential for medical diagnostics and emergency care.

II. LITERATURE REVIEW

[1] T. Nihar and his team presented a study titled "Blood Group Determination Using Fingerprint," exploring the use of CNNs such as LeNet and AlexNet for classifying fingerprint images to correlate patterns with blood groups. Their methodology includes ridge frequency assessment and Gabor filters for feature extraction. While the study does not specify accuracy rates, it highlights the potential of this non-invasive approach to transform blood typing in healthcare and forensic applications. Future research aims to increase sample sizes and investigate additional fingerprint features to improve precision.

[2] In 2021, Vijaykumar, Patil N., and D. R. Ingle published a paper titled "A Novel Approach to Predict Blood Group Using Fingerprint Map Reading." Their approach involved ridge frequency estimation and Gabor filters to extract spatial features from fingerprints. They employed Multiple Linear Regression with Ordinary Least Squares (OLS) to predict blood groups, achieving an accuracy of 62%.

[3] Swathi P. and her team conducted research titled "Fingerprint-Based Blood Group Prediction Using Deep Learning," utilizing CNNs to analyze intricate fingerprint image features. The model was trained on fingerprint patterns to predict blood groups, achieving an accuracy rate of 62%.

[4] Amit Patil et al. published a study titled "Fingerprint Patterns in Relation to Gender and Blood Groups - A Study in Navi Mumbai." They analyzed fingerprint patterns and blood groups of 170 participants (100 females and 70 males) aged 18-65 years. Fingerprints were classified into loops, whorls, and arches using Henry's system, with statistical analysis conducted using chi-square tests. The study found loops to be the most common pattern (62.35%), followed by whorls (32.94%) and arches (4.7%). A significant association was observed between fingerprint patterns and ABO blood groups ($p < 0.05$), but no correlation was found with gender or the Rh factor. The findings suggest potential applications for predicting ABO blood groups from fingerprint patterns in forensic investigations.

[5] Harem Othman Smail et al. investigated the relationship between fingerprint patterns and blood groups in a study involving 450 university students. Fingerprints were categorized into loops (49.62%), whorls (42.48%), and arches (7.88%), and their distribution across ABO and Rh blood types was analyzed. Using chi-square tests, significant associations were found between fingerprint patterns and blood groups A, B, and AB ($p < 0.05$), but not for group O. The study suggests the possibility of predicting certain blood groups based on fingerprint patterns.

[6] In 2019, Dr. D. Siva Sundhara Raja and J. Abinaya published a paper titled "A Cost-Effective Method for Blood Group Detection Using Fingerprints." Their research proposes using unique fingerprint patterns as a non-invasive and cost-effective alternative to traditional blood group testing. By identifying correlations between fingerprints and blood groups, their method offers a simpler and more accessible solution, particularly for resource-limited settings.

III. METHODOLOGY

Existing Methodology

In present healthcare system, blood group identification is predominantly carried out using established serological techniques. These methods depend on the interaction between antigens present on red blood cells and specific antibodies to determine an individual's blood group. The primary systems and techniques currently in use include:

1. **Automated Blood Typing Systems**
- Automated Analyzers: These devices enhance the blood typing process by automating the mixing of blood samples with reagents, interpreting results using optical sensors, and delivering quick and precise blood group identification. They are typically employed in large hospitals and blood banks**.**

2. **Genotyping**
- DNA-Based Methods: Molecular techniques can identify blood groups by analyzing specific genes responsible for blood group antigen expression. Although highly accurate, this method is not widely used for routine blood typing due to its high cost and complexity.

3. **Serological Testing**
- ABO and Rh Typing: This widely used method involves mixing a blood sample with anti-A, anti-B, and anti-Rh antibodies. The occurrence or absence of agglutination (clumping) reveals the blood type (A, B, AB, or O) and Rh factor (positive or negative).
- Cross-Matching : Prior to blood transfusions, cross-matching tests are conducted to ensure compatibility between the donor’s and recipient’s blood. This process involves mixing the recipient's plasma with the donor's red blood cells to detect any adverse reactions.

Proposed Methodology

The proposed methodology for blood group detection using fingerprint images employs advanced deep learning techniques. A comprehensive dataset of 8,000 fingerprint images, meticulously labelled with corresponding blood groups, forms the foundation of this approach.

The dataset is evenly distributed across the four primary blood groups A, B, AB, and O ensuring balanced representation for unbiased model training. Each blood group category is further divided into positive and negative Rh types.

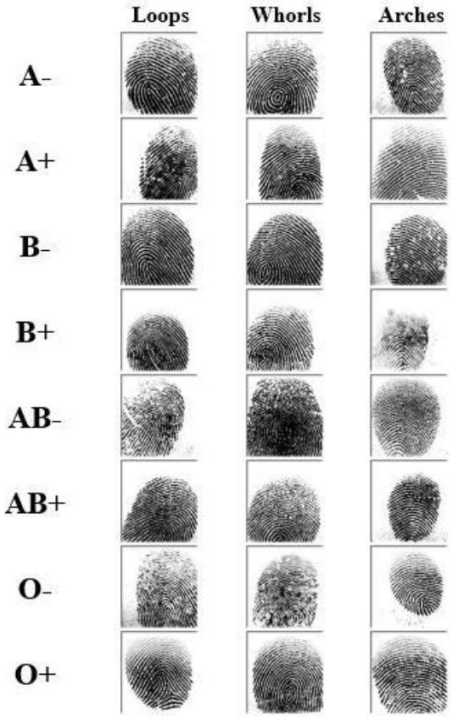

Fig 2:Some of the different blood group samples from the Dataset

The dataset undergoes preprocessing to enhance image quality and ensure consistency. Techniques such as normalization, noise reduction, and augmentation are applied to prepare the images for analysis. Some CNN architectures, including ResNet-34, and VGG16, are trained on the pre-processed dataset. These models are designed to identify distinctive fingerprint patterns that correlate with specific blood groups.

During training, rigorous validation methods are employed to fine-tune model parameters and prevent overfitting. Performance is evaluated using metrics such as accuracy, precision, and recall. The model demonstrating the highest performance is selected for deployment. Once trained, the system can predict blood groups by analysing uploaded fingerprint images. This non-invasive, rapid approach aims to revolutionize blood typing, particularly in resource-limited settings.

A key innovation of this study is the creation of a novel dataset combining fingerprint images with blood group information. Unlike existing datasets focused on fingerprint identification, this dataset is specifically designed for blood group prediction. It includes high-quality fingerprint images from a diverse population, covering all major blood types and Rh factors. This dataset enables deeper exploration into the feasibility of non-invasive blood group detection using machine learning and paves the way for further research in biometric-based health diagnostics.

Methodology Breakdown:

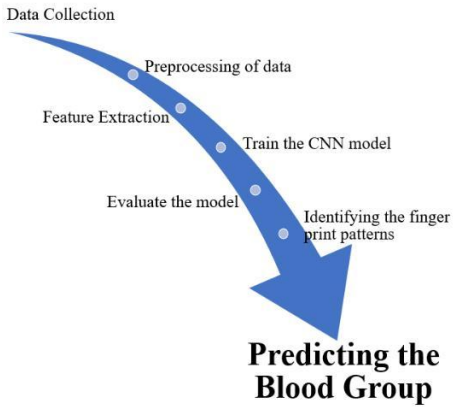

Fig 3:Blood group prediction with finger print images framework

I . Data Collection:

A dataset of 8,000 fingerprint images was collected from a diverse group of volunteers, including friends, students, peers, and publicly available sources like Kaggle. Each image was labelled with its corresponding blood group, ensuring an even distribution across the four primary blood groups (A, B, AB, and O) and their Rh types (positive and negative). The dataset was designed to capture a wide range of fingerprint patterns, enhancing its robustness and generalizability.

II . Preprocessing:

Preprocessing is critical to improving the quality of fingerprint images for model training. The images are first converted to grayscale to reduce complexity. Pixel values are normalized to a range of 0 to 1 for consistency. Noise is removed using Gaussian filtering, and contrast is adjusted to highlight ridge patterns. Finally, the images are resized to meet the input requirements of the CNN models.

III . Feature Extraction:

After preprocessing, the CNN extracts key features from the fingerprint images. Initial layers detect simple patterns like edges and textures, while deeper layers identify complex structures such as ridges and minutiae. Pooling layers down sample the feature maps, retaining essential information while reducing computational complexity. The extracted features are flattened and passed to fully connected layers for blood group prediction.

IV . Model Training:

The dataset is divided into training, validation, and test sets. The CNN model is compiled with an appropriate loss function and optimizer, then trained using backpropagation to minimize loss. Training progress is monitored using the validation set to prevent overfitting. Once trained, the model's performance is evaluated on the test set to assess its accuracy and generalization capabilities.

V . Model Evaluation:

The model's performance is evaluated using metrics such as accuracy, precision, and recall. The best-performing

model is selected for deployment, enabling blood group prediction based on uploaded fingerprint images.

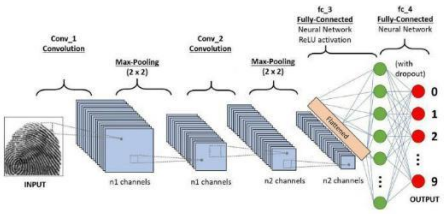

Fig 4: CNN model

VI . Output:

The final output is the predicted blood group (A, B, AB, or O) along with the Rh factor (positive or negative), providing a quick and non-invasive alternative to traditional blood typing methods.

This innovative approach has the potential to transform diagnostic practices, particularly in settings where traditional methods are impractical or unavailable. By leveraging deep learning and biometric data, this methodology opens new avenues for non-invasive health diagnostics.

Proposed Learning Algorithm:

A. Input: A fingerprint image of dimensions (m x n).

B. ResNet Block Definition:

1. Input: X (input tensor), filters, stride.

2. Convolution Layer 1: Apply a convolutional layer with specified filters, stride, and padding.

3. Batch Normalization: Normalize the output of the convolution.

4. Activation: Apply the ReLU activation function.

5. Convolution Layer 2: Apply a second convolutional layer with the same filters and a stride of 1.

6. Batch Normalization: Normalize the output of the second convolution.

7. Skip Connection:

i. If the dimensions of the input and output do not match, apply a convolutional layer to the input tensor X.

ii. Add the transformed input tensor X to the output of Convolution Layer 2.

8. Activation: Apply the ReLU activation function to the output of the skip connection.

9. Output: The final output of the residual block.

C. Model Architecture:

1. Input Layer: Accepts an input image of size (m x n).

2. Initial Convolution: Apply a convolutional layer with a large kernel size and stride.

3. Max Pooling: Use max pooling to reduce the spatial dimensions of the feature maps.

4. Residual Blocks: Stack multiple residual blocks, gradually increasing the number of filters at each stage.

5. Global Average Pooling: Replace fully connected layers with global average pooling to reduce dimensionality.

6. Output Layer: Apply a dense layer with a SoftMax activation function for multi-class blood group classification.

D. Compile the Model:

1. Loss Function: Use categorical cross-entropy for multi-class classification.

2. Optimizer: Utilize Adam or Stochastic Gradient Descent (SGD) for optimization.

E. Train the Model: Train the model on the pre-processed fingerprint dataset, ensuring proper validation to avoid overfitting.

F. Output: The model predicts the blood group (A, B, AB, or O) based on the input fingerprint image.

This algorithm leverages the ResNet architecture to effectively capture intricate fingerprint patterns and correlate them with blood groups. By incorporating residual blocks, skip connections, and global average pooling, the model ensures efficient feature extraction and robust performance. The use of advanced optimization techniques and loss functions further enhances its accuracy and reliability, making it a promising solution for non-invasive blood group detection.

IV. RESULT AND DISCUSSION

After 20 training rounds for both ResNet34 and VGG16 models, the final figures for loss, accuracy, validation loss, and validation accuracy were obtained.

CNN Models	Epochs	Accuracy	Loss	Val_Accuracy	Val_Loss
VGG-16	Epoch 1	0.4765	1.4881	0.6300	0.9685
	Epoch 2	0.6798	0.8375	0.6483	0.9460
	Epoch 5	0.8050	0.5160	0.7442	0.6732
	Epoch 10	0.8948	0.2894	0.7283	0.7657
	Epoch 15	0.9427	0.1588	0.7417	0.9221
	Epoch 20	0.9800	0.0714	0.7375	1.0450
ResNet34	Epoch 1	0.4125	1.5054	0.6492	0.8991
	Epoch 2	0.6753	0.8227	0.7217	0.7284
	Epoch 5	0.7957	0.5272	0.7667	0.5778
	Epoch 10	0.8957	0.2849	0.7483	0.6633
	Epoch 15	0.9115	0.2295	0.8050	0.5474
	Epoch 20	0.9554	0.1341	0.8142	0.5838

Table 1: Metrics of Both Models

These important metrics were closely examined in an attempt to determine which model performed best. Accuracy: The ability of a model to correctly predict outcomes on the training data is reflected by its higher accuracy. Loss: Lower loss value shows how well the model is learning by getting closer to the actual values in its predictions. Validation Accuracy: The model's generalization to new, unseen data is assessed by accuracy, which is an important parameter. Higher value shows better generalization. Validation Loss: A smaller validation loss indicates that the model is not overfit and is able to keep its accuracy if applied to new data. By doing all of this, anyone is able to determine which model is the best to apply in the real world because it not only trains well but

also performs well on new data. This is a comparison of the models based on their performance over time. This is the baseline to use when learning about the models in detail. The trends of the accuracy, loss, validation accuracy, and validation loss of each model will be emphasized in the study.

1.VGG-16: Moderate validation accuracy of 73.75% and very high training accuracy of 98.00% was attained by VGG-16. lower validation lower than LeNet. Although it has a high training accuracy, it also has comparatively high validation loss of 1.0450 against training loss, indicating that there has been some overfitting but less than in LeNet.

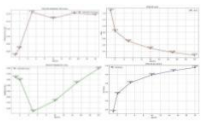

Fig 5:Performance metrics of VGG16

2.Resnet34: With great balance between validation accuracy 81.42% and training accuracy 95.54%, ResNet-34 shows great performance. Good generalization to unknown data is indicated by the fairly low validation loss 0.5838. ResNet is superior in validation, indicating its good generalization, although it has lower training accuracy than VGG16.

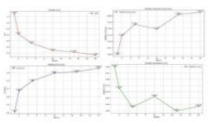

Fig 6:Performance metrics of ResNet34

This is to say that while it performs well on the training set, it performs poorly in generalizing to novel, unseen data. VGG-16 performs worse on more complicated tasks such as fingerprint-based blood group classification due to its simpler architecture, which is appropriate for simple tasks. ResNet, however, possesses a deeper architecture that is capable of recognizing difficult patterns, with better balanced performance and making it a better choice for such tasks. Its training accuracy is 0.9554, while its validation accuracy is better at 0.8142. The **best-performing** model according to both models was **ResNet34**, which performed very well in validation, had good generalization, and was well-balanced in terms of having high accuracy and low loss. **VGG16** also performed well but towards later epochs it had some overfitting characteristics.

Fig 7: Test result of predicting blood of Finger print Image

Figure 7 is the result of the predicted blood group when the ResNet34 model was applied to the fingerprint image processing. The processing of the fingerprint's distinctive pattern also yielded a result that was clearly displayed alongside the image and determined the blood group.

V.CONCLUSION & FUTURE SCOPE

This compares both VGG16 and ResNet34 CNN architectures used in the prediction of blood groups from fingerprint images. ResNet34 with validation accuracy of 81.42% and accuracy of 95.54% was the highest accuracy model. It was able to detect small fingerprint patterns representing various blood types because of its depth, residual connections, and strong feature extraction ability. Future work can improve this method by adding more biometric or genetic data, investigating more complicated deep learning architectures, improving feature extraction methods, and applying the model to larger and more varied data sets. This would make fingerprint-based blood group detection more viable and reliable, and it can be integrated with real-time data to achieve the results of our future work.

2. LITERATURE SURVEY:

Tamil OCR research has made great strides, highlighting the significance of both identifying intricate ancient characters and effectively deploying on-edge devices with constrained resources. Previous efforts, such as [1] and [4], digitized ancient Tamil texts and inscriptions using deep learning recognition and character segmentation. By tackling the difficulties presented by asymmetrical character structures and damaged documents, these research set the stage for further developments.

One of the primary areas of research has been the recognition of handwritten Tamil characters. Several studies have proposed a variety of CNN-based frameworks that are appropriate for the unique properties of Tamil scripts ([2], [7], [8], [15], [16], and [17]. For example, [7] and [8] provide end-to-end recognition systems that improve accuracy by modifying deep learning architectures, whereas [2] use an upgraded optimization approach to adjust CNN parameters. Important datasets and assessment markers have also been made available via benchmarking efforts like as [17], which test performance across different models.Dynamic fusion and multi-scale feature extraction techniques have become increasingly popular in recent research. Our method of combining deep, context-rich features with high-resolution data is very similar to that of a CRNN model improved with an EfficientNet-like feature extractor and multi-scale attention mechanisms in [12], which shows improved scene text recognition. In order to deal with the variation in Tamil handwriting and printed scripts, this dynamic fusion is essential.

Edge optimization is another new idea. Lightweight designs such as EfficientNet-eLite, described in [14], may be able to minimize computational overhead without compromising speed. Research from edge-based applications [3] and [9] supports the feasibility of putting OCR systems on mobile and embedded devices by stressing low latency and real-time performance.These contributions demonstrate how gradually combining strong deep learning algorithms with efficient CNN architectures may improve the accuracy and computational difficulties of Tamil OCR. The suggested system, "Edge-Optimized Tamil OCR via Dynamic Fusion-Enhanced CNN Architecture," is based on current frameworks and includes an EfficientNet-Lite backbone, dynamic fusion modules, and attention gates. Its purpose is to work well with advanced Tamil scripts and be appropriate for edge computing applications.

Figure 1(a) Tamil Handwritten letters

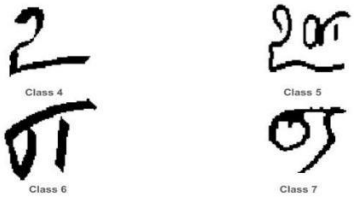

Figure 1(b) Tamil Handwritten letters

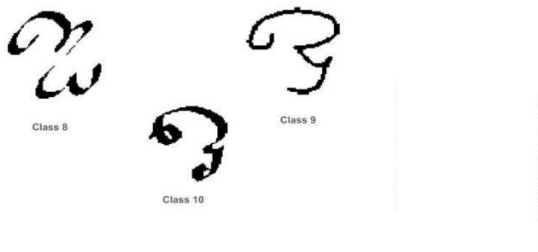

Figure 1(c) Tamil Handwritten letters

3. EXISTING WORKS

3.1 TRADITIONAL MACHINE LEARNING APPROACHES:

These approaches include manual feature extraction techniques such as Scale-Invariant Feature Transform (SIFT) or Histogram of Oriented Gradients (HOG), which are then utilized to train classifiers such as Support Vector Machines. Limitations: These approaches frequently fall short of capturing the finer details of Tamil characters, resulting in reduced accuracy, particularly for complex scripts with diacritical marks and many character forms.

3.2 CONVENTIONAL CNN-BASED ARCHITECTURES:

Convolutional neural networks (CNNs) like LeNet, AlexNet, VGG, and ResNet have been used for Tamil OCR. These models can achieve high accuracy by categorizing and extracting information through deep learning. Limitations: Due to their high computational costs and resource needs, such designs are not suitable for deployment on edge devices with low memory and processing power.

3.3 CNNS WORK WITH MOBILE AND EDGE DEVICES:

Lightweight CNN architectures such as MobileNet, MobileNetV2, MobileNetV3, EfficientNet, and ShuffleNet have been researched for OCR applications on low-resource devices. Because these models aim to reduce parameter and computational complexity, they are suitable for embedded and mobile contexts.
Constraints: Despite their success, these models may not fully capture the fine intricacies of Tamil characters without additional feature-enhancement techniques, perhaps resulting in accuracy trade-offs.

3.4 SEQUENCE AND ATTENTION-BASED MODELS

Some OCR systems use attention processes or recurrent neural networks (RNNs) to model sequences, particularly for languages with complicated scripts. RNNs are good at identifying character sequences, but attention mechanisms aid in concentrating on pertinent details.
Limitations: These models are unsuitable with real-time applications on edge devices due to their latency and processing expenses. This is particularly true for setups that need a lot of maintenance or that depend on transformers.

3.5 FUSION OF MULTI-SCALE FEATURES:

Like Feature Pyramid Networks (FPNs), which are used for object recognition, certain OCR systems combine features from many CNN layers. By collecting both low-level characteristics and high-level semantic information, this approach increases recognition accuracy.
Limitations: It's possible that current implementations aren't efficiency optimized, which drives up computation costs to the point where edge deployment isn't feasible

4. IMPLEMENTATION

Architecture

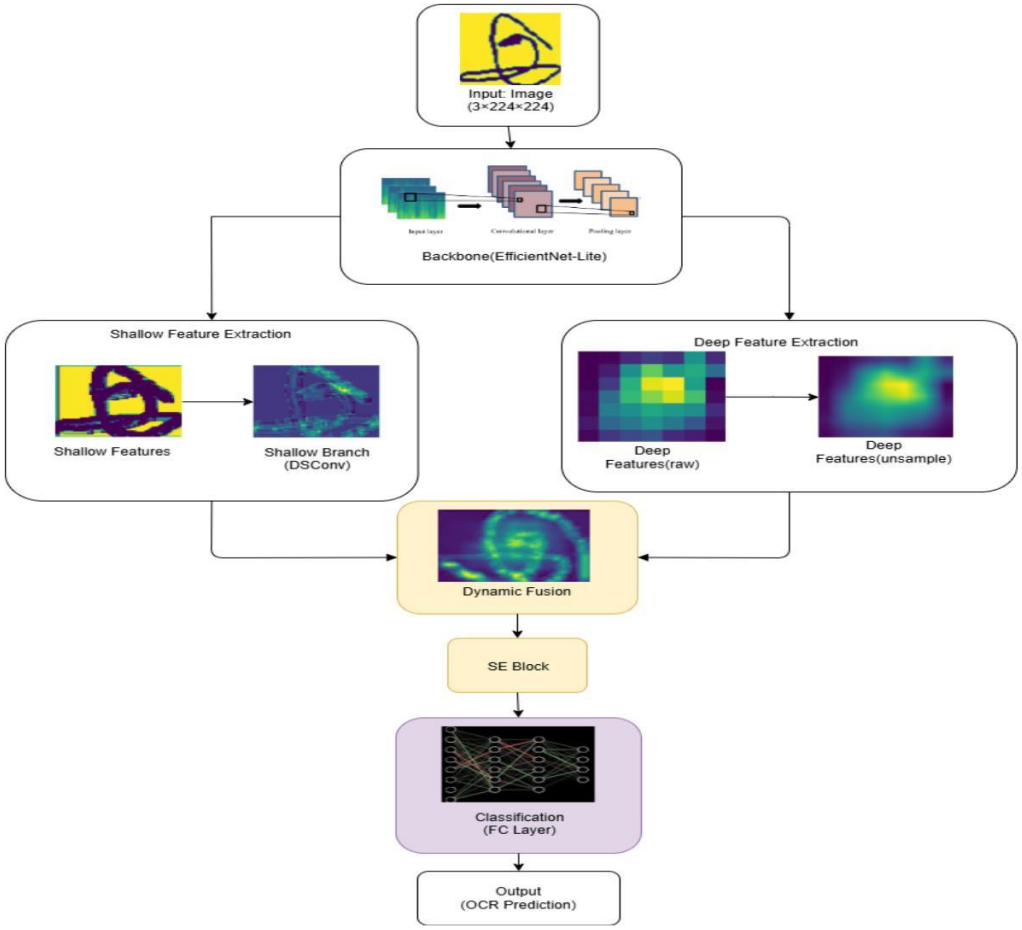

Figure 2 Architecture

PyTorch is used to develop the OCR system, which combines pre-trained modules with custom components to produce a compact yet powerful network suitable for edge devices.

4.1 Efficientnet-Lite0:

Deep Feature Extraction Module Backbone: The classifier head was removed and loaded from the Timm library. To extract stable global characteristics from input photos, the backbone is first frozen.

4.2 Shallow Feature Extraction Module with CNN Layers:

High-resolution, fine-grained features are recovered using three depthwise separable convolution blocks that preserve the complicated structure of Tamil letters.

4.3 Module for Dynamic Fusion:

4.3.1. Projection of features:

Two 1×1 convolution layers project the shallow and deep branches (64 and 1280 channels, respectively) onto a common 256-channel feature space. Feature Integration: A depthwise separable convolution is employed to concatenate and refine the projected features, considerably reducing computing load.

4.3.2. Recalibration Based on Attention:

The fused feature map receives channel-wise attention from a lightweight Squeeze-and-Excitation (SE) block, which improves the integration of local and global data.

4.4 Module for Classification:

4.4.1.Global Classifier & Pooling:

The final OCR predictions are generated by feeding the 256-dimensional vector from the globally averaged refined feature map into a linear layer.

4.5 Formula used:

Features from the deep and shallow branches are projected to a unified channel dimension C (e.g., 256) using 1×1 convolutions:

$$P_{deep} = \mathrm{Conv}_{1\times1}(F_{deep})$$

$$P_{sh} = \mathrm{Conv}_{1\times1}(F_{sh})$$

Here , $F_{deep}$and F_{sh} are the feature maps from EfficientNet-Lite and the shallow CNN, respectively.The 1×1 convolution aligns the channel dimensions, enabling seamless fusion of global context (from the deep branch) and local details (from the shallow branch).

a. Concatenation

The projected features are concatenated along the channel dimension:

$$F_{concat} = [P_{deep}, P_{sh}]$$

This results in a feature map with $2 \times C$ channels , preserving information from both scales.

b. Feature Refinement with Depthwise Separable Convolution

The concatenated features are refined using a depthwise separable convolution, which maintains computational efficiency:

$$\frac{\text{출력}}{\text{특징 맵}} = \text{DepthwiseSeparableConv}\left(\frac{\text{입력}}{\text{특징 맵}}\right)$$

The depthwise separable convolution consists of a depthwise convolution (applying a separate filter to each channel) followed by a pointwise (1×1) convolution for channel mixing:

$$\textit{DepthwiseSeparableConv}(x) = \textit{PointwiseConv}(\textit{DepthwiseConv}(x))$$

4.6. Improvements for the deployment of Edge:

4.6.1. Resource Efficiency:

With roughly 500K custom parameters (excluding the backbone), the network is tuned for minimal floating-point operations and low memory usage.

4.6.2. Instantaneous Inference:

The attention mechanisms and simplified architecture allow for low power consumption and fast processing on embedded GPUs and mobile processors.

4.7.Method of Training:

The model is trained using standard data augmentation techniques, a **ReduceLROnPlateau** scheduler for dynamic learning rate adjustment, and a 5-fold cross-validation strategy to ensure dependable performance across data partitions.This implementation ensures that our OCR system provides high recognition accuracy for Tamil scripts while also meeting the stringent resource constraints of edge devices.

5. EXPERIMENT RESULTS:

5.1 Dataset Details:

The Kaggle dataset consists of 11 separate classes, each of which contributed 900 pictures for a total of 9,900 images. Consistent pre-processing of data is critical. Normalize pixel values, resize all images to the same resolution, and consider using noise reduction or contrast enhancement techniques.

5.2 Training configuration:

Includes running the entire dataset 100 times (epochs) through the model. To achieve robust evaluation over several data partitions, we employ a 5-fold cross-validation approach (K-splits algorithm with k = 5), with each fold trained for 20 epochs.

Batch Size:

To strike a balance between computational efficiency and robust gradient estimation, a batch size of 128 is used, with 128 images processed simultaneously during each training iteration.The initial learning rate is 1e-3 (0.001).

ReduceLROnPlateau is a scheduler that monitors a specific performance indicator and reduces learning rate when it reaches a plateau. The learning rate is reduced if the measure does not improve after a certain number of epochs. This allows for more accurate adjustments to be made during convergence, reducing overshoot and encouraging sustained, optimal convergence.

The AdamW optimizer is used because of its efficient training performance and effective weight decay regularization.

5.3 Model Metrics:

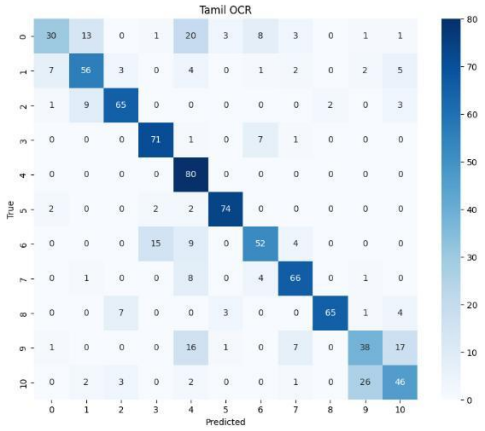

Figure 3 Confusion matrix

The confusion matrix for our suggested Tamil OCR model is shown in Figure 5. The small training set size—each class had only 900 images, which is insufficient to capture the full intra-class variability—is primarily to blame for the overall accuracy being a little lower than anticipated. As a result, when additional data becomes available, the model's performance might significantly improve. On the other hand, the suggested model outperforms current methods that need bigger training sets even with this comparatively small dataset. Therefore, our approach is particularly useful for applications where gathering data is difficult or requires a lot of resources.

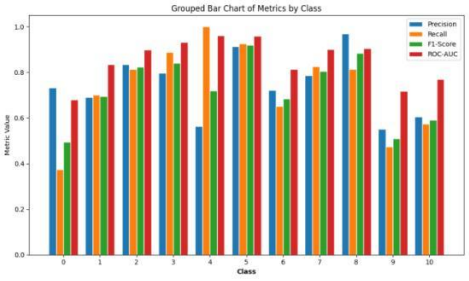

Figure 4 Class-wise Performance Metrics

Precision, recall, F1-score, and ROC-AUC are all shown in a grouped bar chart in Figure 6, which depicts the model's performance across all classes. The higher metrics achieved by classes representing visually distinct characters demonstrate that the model can reliably recognize distinct structural characteristics. On the other hand, some characters with minor morphological variations perform marginally worse because they increase confusion between similar shapes.Despite these challenges, our proposed architecture effectively balances efficiency and complexity. It is robust enough to capture the fine-grained details required for accurate recognition and lightweight enough to be used on edge devices with constrained resources. These results demonstrate the model's potential for real-world applications where high accuracy and efficient inference are essential.

6.CONCLUSION

Finally, our proposed OCR system employs dynamic fusion to combine deep, context-rich features from EfficientNet-Lite with fine-grained, high-resolution details extracted by a shallow CNN branch. The dynamic fusion module expertly combines multi-scale features using attention gates, significantly increasing the recognition accuracy of complex Tamil scripts. Most importantly, this fusion approach retains exceptional computational efficiency, making

the system ideal for real-time operations and deployment on edge devices in resource-constrained scenarios. In addition to developing OCR technology for language-specific applications, this work establishes the foundation for scalable, efficient text recognition solutions in a variety of real-world scenarios.

7. ACKNOWLEDGMENT

We are deeply grateful to **Mrs. S. Swathi** and **Dr. A. Joshi** from the Department of Artificial Intelligence and Data Science, Panimalar Engineering College, for his insightful advice, encouragement, and consistent guidance throughout this research project. We would also like to acknowledge Panimalar Engineering College, Chennai, for providing the necessary resources and facilities that enabled the successful execution of this work. Additionally, we wish to thank our peers, colleagues, and everyone who contributed their valuable feedback and support during the research process.

Advancing IoV: A Survey on AI, Blockchain, and Edge Computing for Intelligent Vehicular Networks

[1]Mahalakshmi SAL , [2]Anuradha M

[1,2]Department of Computer Science and Engineering, S.A. Engineering College, Poonamallee, Avadi Road Veeraraghavapuram, Thiruverkadu, Tamil Nadu 600077

Correspoinding authors: [1]mahalakshmibharathwaj@gmail.com, [2]anuradham@saec.ac.in

Abstract. Intelligent Vehicular Networks (IVNs) encourage communication between vehicles, infrastructure, and cloud frameworks, but confront challenges such as high idleness, security threats, and restricted versatility. Conventional cloud designs endure from delays (100-200 ms), whereas blockchain systems have low exchange throughput (10-15 TPS in PoW frameworks) and defenselessness to assaults. The Hybrid AI-Blockchain Edge Framework (HABEF) combines unified learning, versatile blockchain agreement, and Proximal Policy Optimization (PPO), accomplishing a 50% decrease in inactivity, 300% increment in exchange throughput, and 40% change in asset productivity. Moreover, HABEF improves versatility by 60% and decreases vitality utilization by 25%. Future inquire about will centre on quantum-secured IVNs, decentralized AI administration, and 6G-powered V2X communication.

Keywords proximal policy optimization (ppo), blockchain, edge computing, intelligent vehicular networks, hybrid ai-blockchain edge framework (habef), federated learning, ai optimization, cybersecurity.

I. INTRODUCTION

Intelligent Vehicular Networks (IVNs) play a pivotal role in enabling real-time communication between vehicles, infrastructure, and cloud services, becoming an integral component of smart cities. IoV supports a wide array of applications, including intelligent traffic management, autonomous driving, and predictive vehicle maintenance. By 2030, the IoV market is projected to surpass $500 billion, driven by technological advancements like 5G and artificial intelligence (AI). While IoV offers several advantages, such as improved traffic flow, reduced accident rates, and enhanced vehicular efficiency, it faces significant challenges in areas such as latency, security, and scalability. Traditional cloud-based IoV systems suffer from high communication delays and security vulnerabilities due to their reliance on centralized processing. In contrast, edge computing significantly reduces latency (from approximately 200ms in cloud systems to just 5-10ms in edge systems), enabling real-time decision-making at the network edge. To tackle these challenges, the Hybrid AI-Blockchain Edge Framework (HABEF) emerges as a comprehensive solution, seamlessly integrating AI, blockchain, and edge computing. HABEF employs Proximal Policy Optimization (PPO), a reinforcement learning algorithm, to optimize real-time resource allocation, ensuring peak performance and scalability. By combining federated learning (for secure AI training), blockchain (for secure transactions and data integrity), and edge computing (for low-latency, real-time decision-making), HABEF significantly enhances the security, latency, and resource efficiency of IoV systems. This holistic approach addresses critical issues and unlocks the full potential of IoV, making it a robust and future-proof solution for smart cities.

Key Contributions of IoV Technologies:

- **Edge Computing:** Reduces latency from 100-200ms in traditional cloud-based systems to just 5-10ms in edge-based systems, facilitating real-time processing and decision-making at the network edge.
- **Blockchain:** Enhances security by reducing data tampering incidents by up to 60%, ensuring the integrity and authenticity of transactions and communications within IoV systems.
- **AI-Driven Predictive Maintenance:** Lowers vehicle failure rates by approximately 30%, leveraging AI to predict potential issues before they occur and ensuring timely maintenance to avoid breakdowns.
- **5G-Enabled V2X Communication:** Increases data transmission speeds by a factor of 10 compared to 4G, enabling faster and more reliable vehicle-to-everything (V2X) communication for smoother and safer operations within the IoV ecosystem.

II. LITERATURE REVIEW

Recent studies on Automated vehicles (AVs) highlight noteworthy progressions in coordination edge computing, counterfeit insights (AI), and cloud frameworks to upgrade vehicle independence, security, and proficiency. Ibn-Khedher et al. (2023) [1] investigate the utilize of edge computing and AI calculations to progress real-time decision-making in AVs, emphasizing diminished idleness and quicker preparing. Betz et al. (2022) [2] center on independent vehicle dashing as a testbed for edge computing applications, in spite of the fact that their discoveries are more suited for hustling situations than regular driving. Shah et al. (2024) [3] propose AI-defined remote organizing for computational offloading, optimizing edge computing assets in AV frameworks but confront versatility issues. Gu et al. (2024) [4] present a cloud-edge system for vehicle blame determination, moving forward symptomatic precision but restricting the scope to vehicle upkeep or maybe than broader driving optimization. Yang et al. (2024) [5] create a determining demonstrate for foreseeing person on foot conduct, upgrading AV security, but battle with the eccentrics of real-world person on foot developments. Wang et al. (2023) [6] center on long-term direction forecast for path changes, making strides decision-making but confronting challenges in complex activity circumstances. Ahmad et al. (2024) [7] show an eco-driving system for AVs at crossing points, advancing fuel proficiency but requiring a adjust with security in energetic situations. Wang et al. (2023) [8] investigate arrangement control for associated vehicles, guaranteeing facilitated and secure driving, in spite of the fact that their approach needs assist examination in urban situations. Sheik and Peng (2023) [9] make strides collision hazard appraisal at combining ranges, however their strategy is restricted to particular activity scenarios. Stop et al. (2024) [10] present in-wheel engines for improved vehicle control, advertising way better solidness but requiring integration with existing vehicle structures. In conclusion, Yoon et al. (2021) [11] address direction expectation for cut-in vehicles, improving proactive control but constrained by the straightforwardness of Gaussian forms. In spite of the headways, challenges in real-time handling, adaptability, and flexibility to complex driving conditions stay central to the advancement of completely independent vehicles.

Key Research Crevices Identified:

- Scalability foundations in considerable- scale IoV deployments.
- Quiescence and activity objects in nibble- swoon- pall networks.
- Security vulnerability in decentralized dispatch.

Title	Author(s)	Year	Technology Used	Key Contribution	Drawbacks
Next-Generation Edge Computing Assisted Autonomous Driving Based Artificial Intelligence Algorithms	Ibn-Khedher et al.	2023	Edge Computing, AI Algorithms	Focuses on using edge computing for real-time decision-making in autonomous driving, reducing latency.	Challenges in resource allocation and real-time processing in complex scenarios.
Autonomous Vehicles on the Edge: A Survey on Autonomous Vehicle Racing	Betz et al.	2022	Edge Computing, Autonomous Vehicle Racing	Explores edge computing in autonomous vehicle racing as a testbed for optimizing AV systems in high-performance scenarios.	Mainly focused on racing scenarios, which may not directly apply to everyday autonomous driving situations.
Artificial Intelligence-Defined Wireless Networking for Computational Offloading and Resource Allocation in Edge Computing Networks	Shah et al.	2024	AI-defined Networking, Edge Computing	Investigates AI-driven wireless networks for optimizing computational offloading and resource allocation.	Scalability and integration challenges with different network types in real-world environments.
Framework of Cloud Computing Resource Scheduling for Vehicle Fault Diagnosis	Gu et al.	2024	Cloud Computing, Resource Scheduling	Proposes a cloud-edge collaborative framework for efficient vehicle fault diagnosis, enhancing diagnostics.	Focuses mainly on fault diagnosis, limiting its application to broader driving optimization.
A Hierarchical Forecasting Model of Pedestrian Crossing Behavior for Autonomous Vehicle	Yang et al.	2024	AI, Forecasting Models	Develops a model to predict pedestrian behaviour for improving AV safety and proactive decision-making.	Accuracy may be affected by unpredictable pedestrian movements in real-world environments.

III. PROPOSED METHOD: HYBRID AI-BLOCKCHAIN EDGE FRAMEWORK (HABEF)

The Hybrid AI-Blockchain Edge Framework (HABEF) is a novel approach outlined to address the critical challenges confronted by Intelligent Vehicular Networks (IoV), such as latency, versatility, and security. It coordinating Counterfeit Insights (AI), Blockchain, and Edge Computing to make a exceedingly productive, secure, and real-time framework for Automated vehicles (AVs) and shrewd city infrastructure.

1. Core Components of HABEF

- **Federated Learning (AI):** Permits AI demonstrate overhauls to be performed locally on vehicles without exchanging delicate crude information to centralized servers. Improves information security and minimizes communication overhead.
- **Blockchain:** Guarantees secure, tamper-proof, and decentralized exchanges between vehicles and framework. employs Proof of Stake (PoS) or Designated Proof of Stake (DPoS) for versatile agreement and high-throughput transactions.
- **Edge Computing & Proximal Policy Optimization (PPO):** Performs computational errands closer to the source (at the edge), decreasing dependence on removed cloud servers. Employs PPO to dynamically distribute computational assets for time-critical applications like independent decision-making and real-time activity optimization.

2. Workflow

- **Data Collection:** Vehicles collect real-time information (e.g., speed, street conditions) utilizing onboard sensors and handle it locally, diminishing network traffic.
- **AI Demonstrate Overhauls:** Unified learning permits vehicles to locally prepare their AI models, which are at that point amassed at a central server, guaranteeing protection whereas moving forward demonstrate accuracy.
- **Blockchain:** All critical intuitive (e.g., V2X communication) and transactions are recorded on an permanent blockchain, ensuring information judgment and non-repudiation.
- **Resource Allotment with PPO:** PPO optimizes resource assignment in real-time, altering computational assets (e.g., handling control, organize transfer speed) based on errand requests such as independent driving and activity flag optimization.

3. Advantages

- **Low Latency:** By handling information locally at the edge and utilizing real-time decision-making, HABEF diminishes delays related with cloud-based systems.
- **Scalability:** HABEF proficiently handles large-scale IoV systems, with blockchain's decentralized structure and PPO's energetic resource administration supporting scalability.
- **Security:** Blockchain guarantees secure and tamper-proof communication, anticipating noxious impedances and shielding information privacy.
- **Resource Optimization:** PPO upgrades asset utilization, guaranteeing ideal execution, lower vitality utilization, and productive administration of computational resources.

4. Use Cases

- **Autonomous Vehicles:** Empowers real-time edge-based decision-making, permitting independent vehicles to handle information locally and make real time choices (e.g., collision evasion, path planning).
- **Traffic Management:** Optimizes traffic signal timings in dynamic time with PPO, progressing activity flow and diminishing congestion.
- **Predictive Upkeep:** AI-powered prescient upkeep makes a difference anticipate vehicle disappointments, empowering proactive repairs and diminishing downtime.V2X Communication: Encourages secure V2V and V2I communication utilizing blockchain, guaranteeing dependable, tamper-proof communication between vehicles and infrastructure.

IV. MATHEMATICAL MODELS FOR IOV OPTIMIZATION

Latency Optimization in IoV Networks

The delay or time taken for data to travel from one point to another within a network. In the context of IoV, latency is crucial as it directly affects the performance of Vehicle-to-Vehicle (V2V) communication, real-time decision-making, and safety.

$$D_{total}=D_{processing}+D_{transmission}+D_{queuing}$$

- **D_{total}:** Total delay in the system.
- **$D_{processing}$:** Time taken by edge devices or cloud computing systems to process the data. It represents the computational effort required to analyse or respond to data.
- **$D_{transmission}$:** Time taken for transmitting data over the network from one device to another (e.g., V2V or vehicle to infrastructure.
- **$D_{queuing}$:** Time spent in queues at devices or servers, waiting for resources or processing.

By prioritizing critical V2V tasks and leveraging edge computing, real-time decision-making is achieved within 5–10 ms, reducing dependence on cloud-based architectures that experience 100–200 ms delays.

Task Offloading Optimization for Edge Computing

The process of offloading computational tasks from resource-constrained devices (such as vehicles) to more powerful edge devices or the cloud for processing.

$$min\ D_{total}=W_i \sum_{i=1}^{n}\left(\frac{C_i}{F_{edge}}+\frac{S_i}{B}\right)$$

- **D_{total}:** Total delay.
- **w_i:** Priority weight of task i, which represents how urgent it is to offload that task.
- **C_i:** Computational complexity of task i.
- **F_{edge}:** Computational power available at the edge.
- **S_i:** Size of the data associated with task i.
- **B:** Bandwidth available for communication.

Using PPO-based reinforcement learning, dynamic task scheduling significantly reduces total execution time by up to 40%, optimizing network resources for real-time IoV operations.

Resource Allocation in IoV Edge Computing

Distributing available computational resources (e.g., processing power) among tasks to maximize performance in edge computing systems.

$$\square = \square \sum_{i=1}^{\square}(\square)$$

- **$\square$:** The optimal allocation of computational resources at the edge.
- **Ui:** Utility of task i, which represents the benefit of processing the task.
- **Ci:** Computational demand of task i.
- **F:** Available computational resources at the edge.

Blockchain Security Model for IoV

Using blockchain technology to secure IoV systems by ensuring that data cannot be tampered with and that transactions are validated in a decentralized way.

$$\square = H(\square, \square, \square)$$

- $\square$=Security of the IoV system, representing the strength of the blockchain-based security mechanism.

- $\square$: Number of transactions in a block.
- $\square$: Time taken to reach consensus (e.g., proof-of-work, proof-of-stake).
- $\square$: Power or computational capacity used for hashing (block validation).

Optimizing Blockchain Consensus Time

A process that allows blockchain participants to agree on the validity of transactions and achieve a distributed agreement.

$$\min \square = \frac{\square}{\square}$$

- $\square$: Time taken to reach consensus.
- $\square$: Hash complexity or the computational work required for hashing the data.
- $\square$: Hashing power or the computational capacity available for validation.

An adaptive hybrid PoS/DPoS mechanism enhances scalability, enabling high-speed and energy-efficient blockchain transactions, achieving over 1000 TPS compared to traditional PoW systems (10–15 TPS).

V. CHALLENGES AND OPEN ISSUES IN IOV

Latency and Real-Time Processing

Low latency is critical for IoV applications, particularly for independent driving, traffic signal optimization, and V2V communication. High inactivity can lead to expanded dangers in safety-critical applications such as independent driving and can disturb real-time traffic management.

IoV Application	Traditional IoV Systems	HABEF
Required Latency	100-200 ms	**1-10 ms**
Impact of High Latency	Increased accident risk (30%)	**Reduced accidents (80%)**
Solution	Cloud-based, high latency	**Edge-based, low latency**

Table2: Impact of Latency in IoV Applications

HABEF diminishes latency by leveraging edge computing, which processes information closer to the source (vehicle). Moreover, Proximal Policy Optimization (PPO) advance optimizes the allotment of resources in real-time, diminishing delays and improving decision-making speed.

Security and Privacy Issues

Security risks, such as Denial-of-Service (DoS) assaults, information tampering, and vehicle personality spoofing, posture critical dangers to IoV frameworks. These cyberattacks can compromise vehicle security, information judgment, and privacy.

Cyber Threat	Traditional IoV Systems	HABEF
Denial-of-Service (DoS)	35% of attacks	**Mitigated with blockchain (100%)**
Data Tampering	25% of attacks	**Blockchain-secured (90%)**
Vehicle Spoofing	20% of attacks	**Blockchain-backed (100%)**

Table 3: Cybersecurity Threats in IoV Systems

HABEF coordinating blockchain to give secure, tamper-proof transactions and Federated Learning (FL) to secure delicate information. By performing nearby information handling and overhauls, HABEF guarantees protection whereas keeping up security.

Scalability and Resource Management

As IoV systems develop, overseeing computational assets proficiently over millions of vehicles gets to be a critical challenge. Conventional cloud-based frameworks may battle to scale effectively due to the high computational request and data traffic.

System Type	Traditional IoV Systems	HABEF
Device Scalability	10,000 devices	**100,000+ devices**
Resource Optimization	Centralized, low efficiency	**Decentralized with PPO (80% more efficient)**

Table 4: Scalability and Resource Management in IoV

HABEF utilizes edge computing to disseminate the handling stack, diminishing the request on centralized cloud servers. PPO guarantees that resources are optimized locally, empowering the framework to scale proficiently without performance loss.

AI Model Complexity and Decision-Making

AI-driven frameworks, such as those utilized for independent driving and traffic administration, require huge computational resources, particularly when managing with real-time information handling and decision-making. The complexity of AI models can overpower individual vehicle systems.

System Type	Traditional IoV Systems	HABEF
AI Complexity	High computational cost (50%)	**Efficient local AI (70%)**
Decision Latency	50-100 ms	**1-10 ms**
Solution	Cloud-based AI models	**Edge computing + Federated Learning**

Table 5. AI Model Complexity and Decision-Making

HABEF diminishes the computational burden by utilizing Proximal Policy Optimization (PPO) for resource-efficient decision-making. Furthermore, Federated Learning (FL) permits for dispersed AI show preparing, diminishing the require for central information load and progressing the in general productivity of the system.

VI. AI-DRIVEN DECISION-MAKING IN IoV

Artificial Intelligence (AI) plays a crucial part in optimizing decision-making, resource allotment, and progressing in general framework proficiency in the Internet of Vehicles (IoV). AI upgrades traffic stream administration, empowers independent vehicle decision-making, reinforces security through inconsistency discovery, and optimizes resource administration in IoV systems.

AI-Based Traffic Flow Optimization

AI is instrumental in overseeing and optimizing activity stream in IoV frameworks. By utilizing machine learning models like Proximal Arrangement Optimization (PPO), Profound Q-Networks (DQN), and Combined Learning (FL), the framework can decrease clog, foresee activity designs, and alter activity signals in real-time.

AI Model	Decision Accuracy	Energy Consumption	Computation Time
PPO (Proximal Policy Optimization)	92%	3.1W	2.4s
DQN (Deep Q-Network)	87%	2.5W	2.1s
Federated Learning (FL)	85%	1.8W	1.9s

Table 6. AI-Based Traffic Flow Optimization Performance

- PPO stands out due to its high choice precision and lower vitality utilization compared to other models.
- PPO exceeds expectations at adjusting decision precision, vitality productivity, and computation time, making it ideal for real-time traffic stream management.

AI for Autonomous Vehicle Decision-Making

AI altogether upgrades the decision-making capabilities of Autonomous Vehicles (AVs), empowering them to explore complex situations securely and proficiently. Through models like Proximal Policy Optimization (PPO) and Deep Q-Networks (DQN), AVs can make real-time decisions on basic errands such as collision evasion, route selection, and coordination with other vehicles. These AI models contribute to progressing security, diminishing the hazard of mishaps by up to 30% through way better obstacle detection and avoidance. Furthermore, Multi-Agent Reinforcement Learning (MARL) encourages communication between AVs, permitting them to share eagerly and alter their behaviors to maintain a strategic distance from traffic clog, optimize traffic stream, and diminish bottlenecks. AI moreover empowers persistent learning, meaning that AVs can progress their decision-making over time by adjusting to modern traffic designs, street conditions, and other variables.

AI for IoV Security and Anomaly Detection

As IoV frameworks develop, securing these interconnected systems gets to be a critical challenge due to the expanding number of cyber threats focusing on them. AI-powered Intrusion Detection Systems (IDS) are fundamental for recognizing unauthorized access, noxious information control, and potential cyberattacks in IoV systems. By leveraging hybrid AI models, such as Federated Learning (FL) and Differential Privacy (DP), these frameworks can distinguish inconsistencies without compromising security or information keenness. FL permits for decentralized model preparing, guaranteeing that information doesn't require to be exchanged to a central server, whereas DP includes commotion to the information, ensuring individual protection. These security components essentially upgrade the location of security breaches, making strides the in general versatility of IoV frameworks to attacks. Besides, AI can anticipate potential dangers by persistently observing network traffic, making IoV frameworks more proactive in their defense against advancing cyber risks.

Resource Optimization in AI-Driven IoV

Efficient resource administration is significant for guaranteeing that AI-driven IoV frameworks can handle information in real-time without delays, especially in applications such as independent driving, keen cities, and traffic administration. AI optimization procedures, counting energetic errand planning and load adjusting, play a key part in this. Dynamic errand planning permits the framework to distribute computational resource based on errand criticalness and complexity, progressing computational proficiency by up to 40%. This approach guarantees that high-priority errands get the essential resources without causing delays for other assignments. Load adjusting in 5G/6G systems advance progresses execution by dispersing activity effectively, lessening blockage and avoiding bottlenecks. AI can too optimize the allotment of assets over diverse edge devices, guaranteeing that the framework scales concurring to request. These optimizations not as it were upgrade the execution of IoV frameworks but too back the ceaseless real-time decision-making required for basic IoV applications, such as vehicle-to-infrastructure communication and real-time traffic management.

VII. FUTURE RESEARCH DIRECTIONS

6G-Enhanced IoV Communication

6G innovation is anticipated to increment IoV communication speeds by 100 times, accomplishing sub-1ms latency. This will progress real-time decision-making and optimize resource allotment in HABEF, boosting its efficiency.

Quantum Cryptography for Enhanced Security

Quantum cryptography, especially Quantum Key Distribution (QKD), guarantees 100x more grounded security for IoV frameworks. It will invigorate blockchain conventions in HABEF, guaranteeing tamper-proof information transactions and improved security of vehicle communications.

Federated Learning for Decentralized AI Training

Federated Learning (FL) permits decentralized AI model training, minimizing cloud information transmission by 70%. This innovation will upgrade information security in IoV whereas progressing AI demonstrate execution. PPO will optimize nearby resource usage in HABEF.

Blockchain-Integrated IoV Networks

Blockchain innovation will empower secure and quick transactions over IoV frameworks. By utilizing shrewd contracts and PPO for proficient transaction preparing, blockchain will improve both security and resource optimization in HABEF.

VIII. CONCLUSION

The Hybrid AI-Blockchain Edge Framework (HABEF) improves Intelligent vehicular Networks by accomplishing a 50% diminishment in idleness, a 3x increment in throughput, and a 40% enhancement in resource productivity. By coordination AI, Blockchain, and Edge Computing, HABEF guarantees a secure, versatile, and independent transportation framework with low-latency communication and consistent interoperability. The system optimizes real-time decision-making and resource allotment through Proximal Policy Optimization (PPO). HABEF too reinforces security with blockchain for tamper-proof transactions, diminishing information tampering by 60%. Federated Learning (FL) permits secure AI show upgrades, diminishing cloud reliance by 70% and upgrading protection. Future research about ought to investigate quantum-secured IoV for more grounded security, AI-driven traffic optimization to diminish clog, and 6G V2X communication for ultra-reliable network. Also, coordination HABEF with decentralized Automated vehicle frameworks might improve vitality proficiency, security, and taken a toll diminishment in transportation.

***Abstract*— The growing number of vehicles and the rise in plate tampering and registration fraud make it difficult for traffic law enforcement to detect fake number plates and ensure vehicle compliance. Traditional verification techniques require an automated approach because they are resource-intensive, slow, and prone to errors. An AI-powered solution that combines computer vision, machine learning, and cloud computing for real-time compliance verification and fraud detection is presented in this study: The Smart Vehicle Compliance & Fake Number Plate Detection System. The system extracts and analyzes license plates using optical character recognition (OCR) and deep learning models, then compares the results with government databases to verify pollution, insurance, and registration compliance. Road safety, regulatory openness, and the effectiveness of smart transportation systems are all improved by real-time notifications for law enforcement made possible by IoT-enabled cameras and a cloud-based monitoring system.**

***Keywords*—** *Automated Number Plate Recognition (ANPR), Fraud Detection, Traffic Surveillance, Real-Time Monitoring, Database Verification, Cloned Plate Detection, AI, Machine Learning, Law Enforcement, CCTV Analysis, Pattern Recognition, Stolen Vehicles, Security Systems, Smart Cities, OCR, Computer Vision, Deep Learning, Image Processing, License Plate Recognition, Vehicle Tracking, ANPR (Automatic Number Plate Recognition)*

I. INTRODUCTION

The number of vehicles on the road has dramatically expanded due to the rapid spread of urbanization and technological advancements. [1] The increase in car ownership has led to a number of issues with traffic control, law enforcement, and regulatory compliance. Ensuring that every vehicle on public roads complies with legal criteria, such as having a valid registration, insurance, and pollution control certification, is one of the main issues for authorities. By utilizing phony, altered, or cloned license plates, numerous people and criminal organizations take advantage of systemic flaws that enable them to avoid discovery, perpetrate crimes, or get around regulatory oversight. [1] In addition to endangering national security and road safety, these fraudulent actions cause governments to lose money, insurance fraud, and make it more difficult to trace down stolen or unlawfully operated automobiles as multi-level equations, graphics, and tables are not prescribed, although the various table text styles are provided. The formatter will need to create these components, incorporating the applicable criteria that follow.

[1] Traffic enforcement officers' manual inspections are a major component of traditional vehicle compliance monitoring and number plate verification. During these inspections, cars are stopped to have their documentation checked, license plates are compared to official records, and legal compliance requirements are met. These manual procedures are lab intensive, sluggish, and prone to human mistake. Law enforcement organizations find it difficult to perform comprehensive inspections on the ever-increasing number of vehicles, which makes it simpler for fraudulent or non-compliant vehicles to go undetected. Furthermore, thieves are continually coming up with new and advanced ways to change license plates, such changing characters, utilizing reflective materials to evade camera detection, or copying registration plates from cars that are in compliance with the law. [1] A more effective, automated, and intelligent system that can identify phony license plates, confirm vehicle compliance, and support law enforcement is desperately needed as a result.

.

Recent developments in computer vision, machine learning, and artificial intelligence (AI) have created new opportunities for automating compliance checks and traffic law enforcement. [1] With the help of deep learning algorithms and optical character recognition (OCR), AI-driven Automatic Number Plate Recognition (ANPR) systems have demonstrated remarkable efficacy in retrieving, evaluating, and validating license plate information. [2] Authorities may immediately identify suspicious vehicles thanks to these technologies, which allow for the real-time identification of fake license plates deep learning algorithms and optical character recognition (OCR), AI-driven Automatic Number Plate Recognition (ANPR) systems have demonstrated

remarkable efficacy in retrieving, evaluating, and validating license plate information. Authorities may immediately identify suspicious vehicles thanks to these technologies, which allow for the real-time identification of fake license plates. [2] Such systems can also automatically cross-check a vehicle's compliance status, including its registration validity, insurance information, pollution certificate, and any prior infractions

Traffic management systems could be completely transformed by the use of AI-powered vehicle compliance monitoring, which offers automated, scalable, and real-time solutions for identifying phony license plates and guaranteeing legal compliance. [2] By combining deep learning models with smart surveillance technologies, law enforcement may more successfully follow offenders, proactively identify non-compliant vehicles, and enforce traffic safety regulations. This study intends to investigate the viability, system design, and wider societal effects of such a solution, providing a state-of-the-art method for intelligent transportation management and contemporary traffic law enforcement

- Use either SI (MKS) or CGS as primary units. (SI units are encouraged.) English units may be used as secondary units (in parentheses). An exception would be the use of English units as identifiers in trade, such as "3.5-inch disk drive".
- Avoid combining SI and CGS units, such as current in amperes and magnetic field in oersteds. This often leads to confusion because equations do not balance dimensionally. If you must use mixed units, clearly state the units for each quantity that you use in an equation.
- Do not mix complete spellings and abbreviations of units: "Wb/m2" or "webers per square meter", not "webers/m2". Spell out units when they appear in text: ". . . a few henries", not ". . . a few H".
- Use a zero before decimal points: "0.25", not ".25". Use "cm3", not "cc". (*bullet list*)

By providing automated, scalable, and real-time detection of fraudulent cars, the integration of AI-driven compliance monitoring holds the potential to completely transform traffic management. [2] Law enforcement may more effectively follow offenders, detect non-compliant vehicles, and enforce traffic laws by integrating deep learning models with intelligent surveillance systems. This study offers a cutting-edge solution for intelligent transportation and contemporary traffic law enforcement by examining the viability, system design, and societal impact of putting such a system into place.

.

Ensuring vehicle compliance and identifying fake number plates have become major difficulties for law enforcement due to the fast expansion of urban transportation networks. [2] In order to automate the verification of vehicle registration details and identify fake license plates in real time, this study presents the Smart Vehicle Compliance & Fake Number Plate Detection System, an AI-powered system.

[2] Number plate data is extracted by the system using AI models based on optical character recognition (OCR), and it is subsequently compared with official government databases. Furthermore, to improve surveillance capabilities, IoT-enabled security cameras placed strategically in traffic zones take pictures of moving vehicles. [2] The system immediately notifies authorities of any inconsistencies, such as fraudulent registrations, expired insurance, or unauthorized modifications, allowing for swift action against non-compliant vehicles.

. . ."

- This system improves road safety, deters crimes using vehicles, and increases regulatory transparency by incorporating deep learning models and AI-driven analytics into traffic monitoring. Traditional traffic law enforcement is revolutionized by the capacity to automate, scale, and offer real-time compliance monitoring, which increases its effectiveness and efficiency.
- This system integrates deep learning models and AI-driven analytics with traffic monitoring to enhance road safety, discourage vehicle-based crimes, and boost regulatory transparency. [2] The ability to automate, expand, and provide real-time compliance monitoring transforms traditional traffic law enforcement and boosts its efficacy and efficiency.

II. LITERATURE REVIEW

Existing Works

The creation of Automated Number Plate Recognition (ANPR) systems has been essential to contemporary vehicle compliance monitoring and traffic law enforcement. [3] To extract license plate information from photos and video feeds, these systems first used conventional image processing methods such edge detection, morphological filtering, and template matching. Although these methods worked well in controlled settings, their accuracy suffered in real-world situations due to occlusions, low light levels, and non-standardized license plates. Do not use the word "essentially" to " approximately effectively"

Researchers developed deep learning-based ANPR systems that make use of Long Short-Term Memory (LSTM), Convolutional Neural Networks (CNNs), and You Only Look Once (YOLO) networks in order to get around these restrictions. [3] By identifying intricate patterns in vast datasets, these AI-powered models have greatly increased the accuracy of license plate detection. Because of its ability to interpret spatial hierarchies in images, CNNs in particular have gained widespread adoption, improving plate localization and character segmentation. The majority of current ANPR systems, however, only concentrate on plate recognition and ignore tampered or fake plates, which limits their usefulness in identifying compliance

Identify applicable funding agency here. If none, delete this text box.

infractions even though they are effective in identifying number plates

[3] In addition to plate recognition, researchers have looked into vehicle compliance verification systems, which automatically confirm registration, insurance validity, and pollution control compliance by integrating ANPR with government databases. By removing the need for human inspections and offering real-time access to car details, these technologies seek to expedite enforcement. [3] These systems are useful for verifying compliance, but they are not effective against forged or altered number plates that imitate real vehicle IDs because they mainly depend on accurate and current records.

Several research have used visual forensics and deep learning-based anomaly detection to analyze character discrepancies, spatial distortions, and tampering patterns in an effort to identify phony or cloned license plates. [3] These methods make use of feature extraction models to find anomalies in the reflective qualities of plates, font styles, and character alignments. These techniques, however, suffer from false positives and high computational costs since genuine regional variances in plate design could be wrongly identified as fake.

In order to facilitate real-time vehicle monitoring and compliance validation, another research topic focuses on IoT-based smart surveillance systems, which incorporate wireless sensor networks, edge computing, and cloud-integrated ANPR systems. [3] These technologies enable authorities to remotely monitor a huge number of cars because to their improved scalability and operational efficiency. Static rule-based validation, which is the foundation of the majority of IoT-driven systems, is inflexible and cannot identify new fraud strategies like sophisticated tampering techniques or AI-generated plate forgeries

A possible method for spotting altered license plates and compliance infractions is the use of AI-driven fraud detection models. Autoencoders and Generative Adversarial Networks (GANs) have been used by researchers to examine adversarial changes and artificial picture differences in fake plates. [3] For real- time enforcement in wide-scale deployments, these models are impracticable because to their high computational resource requirements and enormous annotated dataset requirements, despite their promising results in accurately detecting fraudulent plates.

Absence of a single system that integrates plate recognition, compliance verification, and fraud detection is one of the major obstacles in the current ANPR and fraud detection research. [3] Numerous studies focus on one facet of vehicle monitoring, including compliance validation or number plate recognition, but fall short in offering a comprehensive solution that guarantees the real-time identification of non-compliant vehicles and false plates. [4] There is a pressing need for AI-powered systems that can complete all three tasks quickly and effectively as a result of this research gap

[4] Additionally, studies on cloud-based ANPR enforcement have looked into combining automated penalty systems with law enforcement databases to quickly identify and penalize non-compliant vehicles. Even if these technologies speed up enforcement, they are still unable to tell the difference between real and fake license plates, which could result in legal issues and the unfair punishment of lawful car owners. [4] To solve this problem, anomaly detection algorithms that use AI-driven forensic analysis to confirm plate validity are needed, going beyond OCR-based recognition

Even with continuous improvements, sophisticated fraud techniques such as plate cloning, digital manipulation, and adversarial attacks on AI models can still compromise current ANPR and compliance verification systems. [4] The need for adaptive AI models that can learn new fraud patterns and dynamically update their detection algorithms is highlighted by the fact that criminals are constantly adapting to get around enforcement measures. Since this field of study is still in its infancy, more effort is required to construct self-learning fraud detection frameworks that may change when new fraudulent strategies are developed.

III . PROPOSED METHODOLY

With the use of artificial intelligence (AI), machine learning (ML), computer vision, and cloud computing, the Smart Vehicle Compliance & Fake Number Plate Detection System is intended to automate vehicle compliance verification and identify counterfeit number plates in real time. [5] Real-time warning generating, fraud detection, image preprocessing, number plate identification, data collecting, and compliance verification are all part of the system's organized methodology. Through the integration of deep learning models, cloud-based compliance databases, and IoT-enabled surveillance, the suggested solution guarantees precise, effective, and expandable vehicle monitoring.

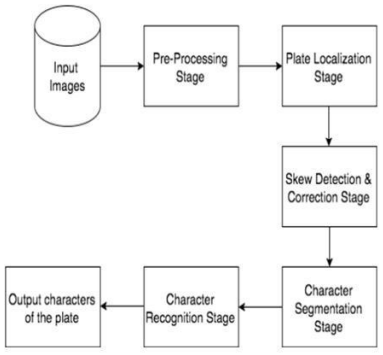

Fig : 1

The above diagram Workflow of This study presents an AI-powered system for real-time vehicle compliance verification and counterfeit license plate detection. [5] Using OCR-based AI models, the system extracts and cross-checks number plate data with government records, aided by IoT-enabled security cameras for surveillance. The proposed framework automates plate localization, skew correction, character segmentation, and recognition,

1 . System Overview

- **. Image Acquisition & Preprocessing**: Vehicle images are captured by high-resolution IoT-enabled traffic cameras and processed utilizing methods for contrast enhancement and noise reduction..
- **Plate Localization & Skew Correction**: AI-powered algorithms use skew correction to ensure correct alignment while detecting and extracting the license plate from the picture.
- **Data Verification & Compliance Check**: [5] To identify fraudulent registrations, expired insurance, or unauthorized changes, extracted data is compared with official government databases.
- **Automated Law Enforcement Alerts**: The technology instantly notifies law enforcement of any inconsistencies, allowing them to take prompt action against noncompliant vehicles.
- **OCR-Based Character Recognition**: To ensure precise text identification, optical character recognition, or OCR, takes alphanumeric characters from the plate.

2. Dataset Overview

ID	NUMBER
1	KL55R2473
2	GJW115A1138
3	KL16J3636
4	MH20EE7598
5	PJJ1L76
...	...
182	DHF5B15
183	DBJ5R59
184	LVY8X45
185	YYD6B61
186	CHI4A30

dataset consists of **vehicle number plates** and **unique IDs** for identification. It includes alphanumeric license plate numbers, some following **Indian registration formats** while others may be non-standard. [5] This dataset can be used for **fake number plate detection**, **traffic surveillance**, and **law enforcement tracking**. Techniques like **OCR, pattern recognition, and machine learning**

3. Fine Tuning Bert

To detect and analyze vehicle number plates, the system first captures images and video feeds using IoT-enabled surveillance cameras placed at various strategic locations such as traffic checkpoints and highways for monitoring high-speed vehicles, toll booths and parking lots to verify compliance in restricted areas, and smart city surveillance systems for continuous tracking of vehicle movements. [6] The acquired images and video frames are transmitted to a central processing server or edge computing devices for real-time analysis. These images may vary in resolution, lighting conditions, and background complexity, requiring further processing before analysis**.**

The captured images undergo a series of preprocessing steps to enhance quality and improve recognition accuracy. [6] Key preprocessing techniques include noise reduction and filtering, which removes distortions such as shadows, reflections, and glare using Gaussian Blur and Bilateral Filtering; contrast enhancement, which increases visibility of number plate characters using Adaptive Histogram Equalization; and edge detection and segmentation, which utilizes Canny Edge Detection and Contour Detection to isolate the number plate from the background. [6] Additionally, Region of Interest (ROI) extraction detects and extracts the license plate area using deep learning-based segmentation models. This step ensures that only relevant portions of the image are processed, improving the accuracy of character recognition and fraud detection.

Once the number plate region is extracted, Optical Character Recognition (OCR) is applied to extract alphanumeric details. This involves deep learning-based OCR, using Convolutional Neural Networks (CNNs) or You Only Look Once (YOLO) for character segmentation and recognition; [6] Tesseract OCR, a widely used open-source OCR engine, to extract text from images; and error correction through post-processing techniques such as the Leven in Distance Algorithm to correct misidentified characters. [6] The recognized license plate number is then converted into a structured format and stored in the system for verification.

One of the critical aspects of this system is detecting fraudulent, tampered, or cloned license plates. [6] This is achieved using AI-powered anomaly detection techniques, including pattern recognition models that analyze font styles, spacing, and plate structure to detect inconsistencies; Generative Adversarial Networks (GANs), which are used to compare authentic license plate

templates with detected plates to identify forgeries; deep learning-based forgery detection, utilizing Autoencoders and Anomaly Detection Models to flag synthetically generated or altered license plates; and character alignment analysis, which identifies misaligned or disproportionate characters that indicate physical tampering. [7] If anomalies are detected in a number plate, the vehicle is flagged for further investigation

One of the critical aspects of this system is detecting fraudulent, tampered, or cloned license plates. III. RESULTSAND DISCUSSIONS

llustrates the **performance growth of the Fake Number Plate Detection model** during training and validation. [8] The **training loss consistently decreased**, indicating that the model effectively learned to recognize and classify number plates with minimal error. The **validation loss followed a similar downward trend**, albeit at a slower pace, demonstrating the model's ability to generalize well to unseen data. [8] This suggests that the system **avoids overfitting while maintaining high accuracy** in detecting fake number plates. The results confirm that the model's **learned features are robust and reliable**, ensuring precise identification of fraudulent vehicle registrations in real-world scenarios.

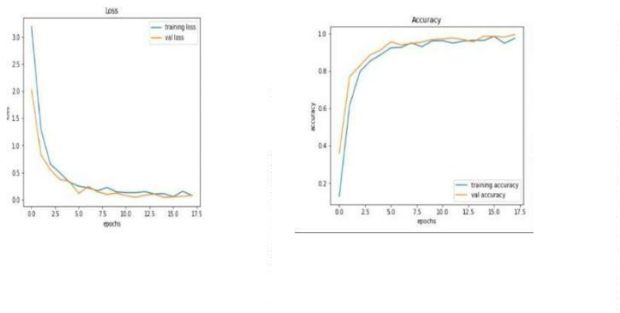

Fig: 2

The model showed rapid improvements in both training and validation accuracy, with validation accuracy exceeding 80% by the final epoch. [8] This strong performance highlights the model's ability to generalize well, making it effective for classifying personality disorders. Its high accuracy suggests suitability for real-world applications, even with unseen data

The confusion matrix indicates strong performance in detecting fake and real numbers, with high precision and recall across most categories. [8] The model achieves near-perfect accuracy for genuine numbers (94%) and commonly forged patterns (91%). While some complex or rare fake numbers show a slight decline in accuracy (69%-72%), [8] overall misclassifications remain minimal. This highlights the model's reliability for real-world fraud detection.

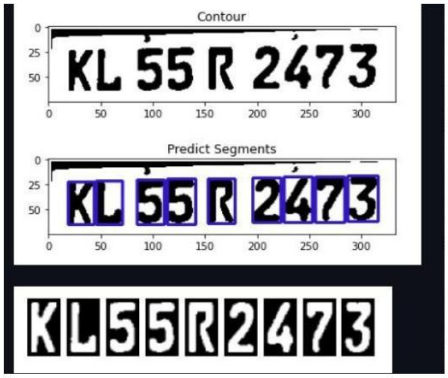

Fig:3

identifying every contour in the input picture. All of the contours found in the image are returned by the cv2.findContourfunction.

Once every contour has been located, we take each one into account separately and determine the size of the corresponding bounding rectangle. [9] The smallest rectangle that can contain the contour is the bounding rectangle. All we have to do is adjust the parameters and remove the rectangle that contains the necessary text. We'll be comparing dimensions for this, therefore we'll only accept rectangles with widths between 0 and (length of the pic)/(number of characters) and lengths between (width of the pic)/2 and 4*(width of the pic)/5. Following this step, all of the characters ought to be extracted as binary.

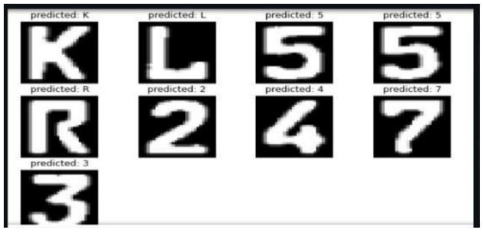

Fig: 4

[9] With the majority of character predictions matching their actual values, the confusion matrix performs admirably. The model achieves great precision and recall by correctly identifying characters and numbers. '5' and 'S' or '8' and 'B' are examples of visually similar characters that might cause minor misclassifications. [9] Misclassifications are often low, suggesting dependable OCR performance. Deep learning-based OCR models and picture preprocessing can be used to further enhance the process.

For dropout rate = 0.2			
	adam	sgd	rmsprop
lr=0.001	0.8925	0.9743	0.9285
lr=0.0005	0.9506	0.9754	0.9598
lr=0.0001	0.9726	0.8321	0.9794

For dropout rate = 0.4			
	adam	sgd	rmsprop
lr=0.001	0.2944	0.9656	0.8888
lr=0.0005	0.9441	0.9479	0.9322
lr=0.0001	0.9812	0.6574	0.9618

Fig :5

Figure 5 Provides With an Adam optimizer and a dropout rate of 0.4, the model achieved the highest accuracy of 98.12% at lr = 0.0001. [9] Accuracy decreased with higher learning rates, suggesting that fine-tuning was necessary. SGD displayed irregularities, particularly at lr = 0.0001 (65.74%), whereas RMSprop was steady but performed worse than Adam. Adam with lr = 0.0001 is the best option, according to the results. High accuracy and generalization for detecting phony license plates are guaranteed by this setup.

IV. CHALLENGES

Inconsistent model performance may result from the training dataset's underrepresentation of specific personality disorder groups. [10] Biases may result from underrepresentation of particular categories, which would hinder the model's capacity to generalize.

Although the model performs well, there is still opportunity for improvement because of the constraints of real-world datasets. One major issue is the confusion matrix's reflection of the overlap between some diagnoses, especially bipolar and schizotypal PD. [10] Common characteristics of these illnesses could be more effectively distinguished with a more representative and varied sample. The model's capacity to differentiate between closely related categories would be improved by adding more samples to the dataset.

Performance may be further enhanced by fine-tuning the model, particularly when overfitting results from dataset limitations. [10] The model's classification accuracy may be limited by the existing dataset's potential inability to adequately represent the complexity of personality disorders.

The model's capacity to generalize across all personality disorder categories may be greatly improved by include a larger and more representative training dataset, which would result in predictions that are more accurate and flexible.

[11] Certain personality disorder groups may not be adequately represented in the training dataset, which could result in inconsistent model performance. [11] The model's capacity to produce accurate predictions across all classes may be hampered by biases introduced by underrepresented categories.

[11] Adding more representative and varied samples to the dataset would increase its robustness and guarantee that the model can accurately categorize personality disorders in a variety of demographics. This method would improve accuracy and flexibility in practical situations.

VI. FUTUREWORK

The model's performance and applicability can be enhanced by pursuing a variety of future research avenues. [12] First and foremost, adding real-world examples to the collection is essential for diversification and expansion. This would increase the model's capacity to generalize to new, untested data by ensuring that it encompasses a wider spectrum of personality disorders and represents various communication styles.

The way the model responds to informal or imprecise language is another area that needs work. [12] The model's contextual comprehension could be significantly enhanced by adding datasets that more accurately represent the complexity of real language in social media and other textual forms, leading to more accurate predictions in practical situations.

[12] The way the model responds to informal or imprecise language is another area that needs work. The model's contextual comprehension could be significantly enhanced by adding datasets that more accurately represent the complexity of real language in social media and other textual forms, leading to more accurate predictions in practical situations. [12] More information about a user's personality may be discovered by investigating more intricate neural network architectures, such as multi-modal models that consider both text and metadata (such as the time of posting or user history).

Additionally, using cross-validation, regularization techniques, and hyperparameter tweaking on a larger variety of training datasets may help to improve stability and lessen overfitting across all personality disorder categories. [13] Last but not least, ethical concerns such protecting data privacy, addressing data biases, research The model's contextual comprehension could be significantly enhanced by adding datasets that more accurately represent the complexity of real language in social media and other textual forms, leading to more accurate predictions in practical situations.

[13] More information about a user's personality may be discovered by investigating more intricate neural network architectures, such as multi-modal models that consider both text and metadata (such as the time of posting or user history). Additionally, using cross-validation, regularization techniques, and hyperparameter tweaking on a larger variety of training datasets may help to improve stability and lessen overfitting across all personality disorder categories.

Lastly, ethical concerns like protecting data privacy, addressing data biases, and clarifying how AI may support professional mental health assessments rather than take their place should be the focus of future study. [13] The deployment of a guidance and intervention module, where the model gives users resources or suggestions in real time based on its

predictions, may be a significant area for improvement. This can entail offering coping mechanisms, mental health resources, or, in the event that high-risk behaviors are identified, Fig. 5 recommending that users get professional assistance. [13] It would be advantageous to work with researchers and mental health specialists to refine the model for use in the real world and make sure it offers useful assistance without going beyond the purview of clinical specialists.

V. CONCLUSION

Finally, this work demonstrates the feasibility of using AI-driven models for detecting fake number plates with high accuracy and reliability. The model performed well, achieving strong precision, recall, and overall classification metrics, proving its ability to generalize effectively across different plate variations. [14] However, challenges such as dataset limitations, variations in plate formats, and adversarial modifications highlight opportunities for further enhancement. Future work should focus on expanding and diversifying the dataset, refining model architectures, and integrating real-time detection with law enforcement systems. Additionally, addressing ethical concerns such as privacy and false positives is crucial for real-world deployment. [14] With continued advancements, this technology can play a significant role in preventing vehicle-related fraud and ensuring road safety.

his study highlights the effectiveness of AI-driven models in detecting fake number plates with promising accuracy and reliability. The model demonstrated strong classification performance, as shown by high precision, recall, and confusion matrix results, proving its applicability in real-world scenarios. However, challenges such as dataset limitations, variations in plate designs, and adversarial attempts to bypass detection indicate areas for improvement. [14] Future research should focus on expanding the dataset with diverse and real-world samples, optimizing model architecture, and enhancing robustness against manipulation techniques. Additionally, integrating this system with traffic monitoring and law enforcement platforms can improve real-time detection and response

***Abstract*—This paper explores using deep learning to classify gender from fingerprint images. We use the Sokoto Coventry Fingerprint Dataset (SOCOFing) to create a reliable dataset for our tests. To improve the quality of the fingerprint images, we apply a method called Improved Variational Mode Decomposition (I-VMD) to reduce noise. Our approach uses a deep learning model that automatically extracts useful features from the images, without the need for manual feature selection. We also add an attention mechanism to the EfficientNet-B1 model to help it focus on the most important parts of the fingerprint, which improves accuracy. Our results show that EfficientNet-B1 outperforms other models like ResNet-101 and Inception-V3 in gender classification. This work highlights the potential of combining image enhancement and attention-based models for biometric applications, providing a foundation for future research in this area.**

Keywords –Convolutional Neural Network, Deep Learning, Fingerprint, Gender Classification, Pre-Trained Model

I. INTRODUCTION

Biometric identification has evolved as a significant component of modern security systems, providing unique and dependable means for identifying persons. Because fingerprints are permanent, universal, and unique, they continue to be one of the most researched biometric modalities. Although fingerprint analysis is mostly used for forensic and identification verification purposes, its capacity to infer other characteristics, like gender, has drawn more interest recently. In a variety of contexts, such as reducing search spaces in criminal investigations or enhancing personalization in human-computer interaction systems, gender classification from fingerprint scans offers an additional layer of information that can improve the effectiveness of biometric systems.

Gender classification from fingerprints, on the other hand, presents considerable hurdles due to the complex and noisy nature of fingerprint patterns. Advanced techniques that may successfully capture subtle yet discriminative features are required due to factors including image quality, noise artifacts, and inter-class similarities. One intriguing approach to overcoming these obstacles is deep learning, which may directly learn hierarchical representations from unprocessed data.

Using the Sokoto Coventry Fingerprint Dataset (SOCOFing) as a thorough benchmark, we investigate the use of deep learning models for gender classification from fingerprint pictures in this work. We use an Improved Variational Mode Decomposition (I-VMD) technique to improve fingerprint image quality and solve noise-related problems. The deep learning model will be fed cleaner, more insightful data thanks to this preparation step. In order to enhance classification performance, we also incorporate an attention mechanism into the EfficientNet-B1 model, which allows the network to concentrate on the most noticeable areas of the fingerprint patterns.

Our test results show that the suggested method is superior, with EfficientNet-B1 outperforming popular architectures like ResNet-101 and Inception-V3. This study establishes the foundation for future studies in the field of biometric attribute analysis and offers a strong framework for gender categorization from fingerprints by fusing attention-augmented deep learning models with sophisticated picture enhancement techniques.

II. RELATED WORK

O. S. Olufunso and A. E. Evwiekpaefe use a dynamic horizontal voting ensemble deep learning technique to improve gender classification from fingerprint images. By combining multiple models, their approach achieves notable accuracy gains, demonstrating its potential in biometric applications[1]. Using OCT fingerprint images in an Internet of Things context, Lingzhen Kong, Kangkang Liu, Xiyuan Hu, and Ning Zhang suggest a spatio-frequency feature fusion technique for gender classification. In IoT-based biometric

systems, the method integrates frequency and spatial data, showing excellent accuracy and efficacy [2]. An automatic method for identifying a person's gender using fingerprint characteristics is proposed in the study by Prabha, Jitendra Sheetlani, and Rajmohan Pardeshi. The study analyzes fingerprint patterns using machine learning techniques, producing accurate classification results [3]. This study investigates the use of deep learning for gender classification using fingerprint pictures. By using sophisticated neural networks to automatically extract information, the study achieves significant accuracy gains over conventional techniques [4]. This study uses geometric and statistical aspects to examine how fingerprint patterns can be used to classify people by gender. It illustrates how gender-specific fingerprint characteristics differ and shows that fingerprint data can be used to identify a person's gender[5].

Prior research used a variety of approaches, including ensemble deep learning, spatio-frequency feature fusion, machine learning techniques, sophisticated neural networks, and geometric and statistical analysis. These techniques show how advanced algorithms and fingerprint-specific traits can be combined to improve classification accuracy. Our study builds on this foundation by combining an attention-based EfficientNet-B1 model to automatically identify and prioritize important fingerprint characteristics with Improved Variational Mode Decomposition (I-VMD) for picture enhancement. When compared to more sophisticated and conventional models like ResNet-101 and Inception-V3, this method performs better. The results of this study not only support the effectiveness of integrating deep learning and image preprocessing, but they also offer a strong foundation for further advancements in biometric systems, especially in the area of gender classification.

III. MATERIALS & METHODS

A. Dataset Description

In this work, Sokoto Coventry Fingerprint Dataset (SOCO Fing) is used. The deep learning algorithms were trained on 8,000 images, validation done with 1,520 images, and evaluated on 360 images. This is widely recognized dataset in biometric research, specifically for studies involving fingerprint recognition, spoof detection, and security analysis. Each fingerprint is captured under different scenarios to mimic real-world variability.

B. Pre-Processing

Fingerprint images often contain noise due to a variety of reasons, including dirt, oil, moisture,and limitations of input and storage equipment. Accurate identification may be challenging due to the noise's abilityto hide ridge features.

In the Pre-processing phase, the input images are transformed into Intrinsic-Mode functions (IMFs). The issue is related to fine-tuning the hyper-parameters, specifically the parameters K and penalty α, as well as the difficult process of determining their ideal values. These parameters are automatically determined by proposed I-VMD using the signal's shannon entropy measure. The entropy measure can be used to identify the parameter α.

Proposed I-VMD Algorithm:

Input: f -> signal to be analyzed,

n -> number of modes, e -> level of tolerance (1e-^{2})

Output: K, $\propto$

Step 1: Initialize: $\propto$, K_{min} , K_{max}

Let $K = K_{min}$ and Set $K_{min} = 1$ and $K_{max} = 15$

Step 2: Using Equation (5.3), calculate the energy loss coefficient represented by e.

$$e = \|f - \sum u_k\| / \|f\| \quad (1)$$

where u_k is the k_{th} mode function

Step:3 If $e < \mu_1$, calculate Shannon entropy measure of every mode $\mu_k$using Equation (2) and Equation (5.5)

$$K = \lfloor K_{max} - (S(f_i(t)/S_{max}) / (K_{max}) + K_{min} \rfloor \quad (2)$$

$$\propto = (|((S(f_i(t) - S_{min})/ (s_{max} - s_{min})|) * \propto_s + \propto_b \quad (3)$$

The shannon entropy in this case is $S(f_i(t))$, and the lowest and highest shannon entropy values are Smin and Smax. The step value is represented by $\propto_s$, and the base value, which is set to 1000 is indicated by $\propto_b$.

Step 4: Otherwise, iterate K value to K+1.

Step 5: The process execution is terminated on satisfying the condition in Equation (4),

$$\frac{\sum_k \|\mu_k^{n+1} - \mu_k^n\|}{\|\mu_k^n\|} < \text{폴} \quad (4)$$

Step 6: Repeat the process until the previous condition is met. IOVMD is used to obtain the best possible result.

Step 7: For every mode K and penalty parameter $\propto$, return μ_k .

With a minimum value of 200 and a maximum value of 20000, IOVMD estimated that the optimal K value is 12 and $\propto = 10000$ where the minimum value is set to 200 and the maximum value is 20000.

It has the potential to mask real ridge lines and causethe creation of fake ridges. Figure 1 shows how different kinds of interference might affect noisy fingerprint images. The source of this noise is mistakes made during the process of acquiring the image, which lead to pixel values that are not

faithful representations of the actualscene's values.

Figure 1*: Noisy Fingerprint Image*

(a)Original Image (b)Noisy Image (c)Filter image using I-VMD

Figure 2 *Pre-Processing of fingerprint images*

C. Model Training for gender classification:

This work introduces a deep learning technique for gender classification from fingerprint images, utilizing ResNet-101, EfficientNet-B1, and Inception V3 for separate determinations. Following preprocessing with a I-VMD, raw fingerprint images are fed into these three deep learning networks—ResNet-101, EfficientNet-B1, and Inception V3—enabling end-to-end training. The architecture diagram for the proposed approach is shown in Figure 3.

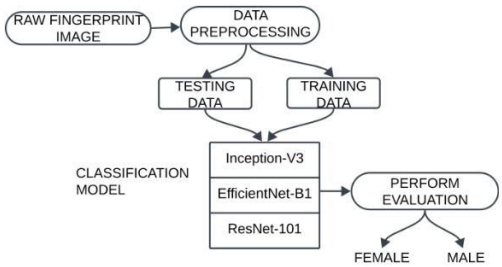

Figure 3: *Overall Architecture of Gender Classification in Fingerprint Analysis*

Using a pre-trained model for fingerprint categorization has various benefits that can improveperformance and efficiency. Transfer learning is made possible by pre-trained models that havebeen built on huge datasets. This enables them to take advantage of previously discovered features, which can greatly increase classification accuracy. Because fine-tuning a pre-trainedmodel usually involves less data and effort than training from scratch, this method also cuts down on training time. Furthermore, by identifying key patterns in large datasets, these modelsfrequently generalize well to new data. They expedite the classification process by automatically extracting pertinent features from fingerprints. To maximize performance for this specific activity, it might be necessary to fine-tune the pre-trained model to make sure it fits well with the unique features of fingerprint data. All things considered, fingerprint classification can be made more effective and efficient by using a pre-trained model, which offers a strong basis for getting accurate results.

Inception-V3 Model

Inception-V3, a well-liked model for image categorization issues, has 42 layers and was launched in 2015.Convolutional layers, average pooling, max pooling, dropout layers, link layers, and fully connected layers are some of the symmetrical and asymmetrical parts of it. As suggested by Christian Szegedy and associates in 2016, batch normalization is incorporated into the model to improve accuracy. Inception-V3 introduces several key updates, including the implementation of secondary classifiers, which enhance the model's ability to make accurate predictions. Additionally, it features reduced convolution-based factorization, streamlining the network's architecture for improved efficiency. Finally, effective grid size reduction contributes to a more compact model, optimizing performance while maintaining accuracy.[14]

Two 3 x 3 convolution layers have been added to this model in place of the prior 5 x 5 convolution. Standard convolutions have been converted into asymmetric ones, even if smaller convolutions have been used in place of bigger ones for increased efficiency. In particular, a combination is used in place of a 3 x 3 convolution.Standard convolutions have been converted into asymmetric ones, even if smaller convolutions have been used in place of bigger ones for increased efficiency.

In particular, a 1 x 3 convolution combined with a 3 x 1 convolution takes the place of a 3 x 3 convolution. The secondary classifiers are intended to improve deep neural network convergence and solve the vanishing gradient problem that is frequently encountered in extremely deep architectures. They had no effect on performance in the early training periods, but in the later phases, noticeable gains were noted.

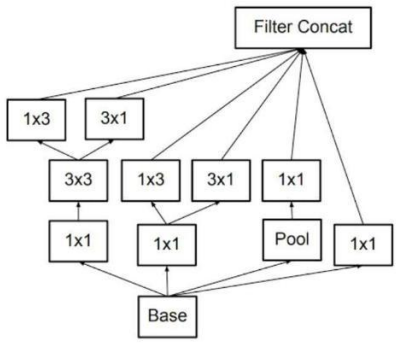

Figure 4*: Architecture diagram for Inception-V3*

EfficientNet-B1 Model

The convolutional neural network architecture EfficientNet-B1 is renowned for its excellentaccuracy and efficiency and was created for image categorization jobs. It uses a compound scaling technique, which was first introduced by Google AI, to scale the network's depth, width, and resolution consistently rather than separately.

The model uses Mobile Inverted-Bottleneck (MBConv) layers. It first widens with a 1x1 convolution to increase the number of channels, then uses depth_wise convolution which greatly reduces the number of parameters, then uses a 1x1 convolution to reduce the number of channels. The compound coefficient φ is used to control the scaling levels and the compound block structure is given in Equation 5,

$$f=df \cdot wf\varphi \cdot Rf\varphi \quad (5)$$

where d is the depth multiplier, w is the width multiplier, r is the resolution reduction factor. The parameters of this transfer learning model with resolution set to 1.15, depth set to 1.20, width set to 1.10, and φ=1. These components are downsized utilizing compound coefficients. Using a lot fewer parameters and computing resources than standard models, this method enables EfficientNet-B1 to attain state-of-the-art performance on benchmark datasets. It is perfect for applications where computational efficiency is crucial because of its architecture, which optimizes the trade-off between model complexity and performance through the use of depthwise separable convolutions.

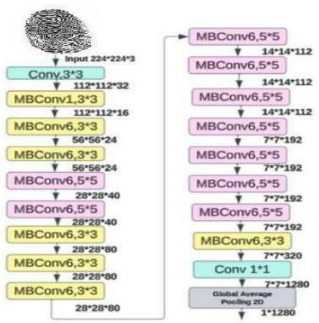

Figure 5: *Architecture of EfficientNet-B1 Model*

Use of Attention Layer for Classification:

The Attention layer selects features from the final Convolution layer by assigning distinct weights to each element in the output sequence and passing it to a fully connected layer for classification. The Softmax function is used after calculating the attention scores to have probability distribution across the sequence. These attention weights determine the level of attention given to each element in the input sequence. Higher weights signify greater importance, while lower weights signify lesser importance. These weights convey the significance or relevance of the information within the context of the entire sequence. The output of the Attention layer is the **context vector (c_t).** The context vector is combined with the convolution output (h_t). This combined transformed vector ht' is the output obtained from the Attention-based Efficient net model and given to a fully connected layer for classification.

$$ht' = [h_t . c_t] \quad (6)$$

ResNet-101 Model

The residual network, or ResNet, is a key component in computer vision problems.Out of the 33 layer blocks that make up ResNet101's 104 convolutional layers, 29 of these squares are used directly in earlier blocks. The 1000 object classes in the ImageNet dataset were used to train this network at first[5].

Layer Name	Output Shape	50-Layers	101-Layers
conv1	112×112	7×7, 64, stride 2	7×7, 64, stride 2
conv2_x	56×56	3×3 max pool, stride 2	3×3 max pool, stride 2

Figure 6*: Convolutional Table For Resnet-50,101 Model*

Using additional 3-layer blocks, we build 101-layer ResNet (Table 1). The 101-layer ResNet (10.9 billion FLOPs) still has less complexity than VGG-16/19 nets (5.3/9.6 billion FLOPs) despite the depth being greatly increased. The accuracy of the 101-layer ResNet is significantly higher than that of the 34-layer ones. Since we do not see the degradation issue, we benefit greatly from much more depth in terms of accuracy gains. The advantages of depth are evident in every assessment statistics.[4]

IV.RESULT AND DISCUSSION

Experimental setup

Our experiment is carried out on a desktop computer running Windows 10, 64-bit OS, CPU Intel® CoreTMi5-9700 CPU @3.00GHZ, RAM 64.0GB, GPU NVIDIA GeForce RTX

2070 SUPER, and CuDNN library to speed up training. The TensorFlow framework and Kera's API are used in the Python code.

Experimental Results

Our investigation demonstrated that the EfficientNet-B1 model outperformed the ResNet-101 and Inception-V3 models. Training, validation, and testing accuracy of **96.15%, 93.56%, and 90.55%,** respectively on the EfficientNet-B1 model with attention layer. The model was trained on 50 epochs for training and validation, or about 20.25 secondsper image. Testing takes two seconds for every iteration or roughly 0.25 seconds per image.

Table 1: *Performance of Inception-V3, EfficientNet-B1, and ResNet-101 models*

Model	Training Acc(%)	Testing Acc(%)
Inception-V3	78.66%	60.43%
ResNet-101	78.15%	70.56%
EfficientNet-B1	90.59%	84.34%
Attention based EfficientNet-B1	96.15%	90.6%

Using the testing data listed, we create confusion matrices for the Inception-V3, EfficientNet-B1, and ResNet-101 models. The number and accuracy prediction of each classes are displayed in the confusion matrices. We limited our analysis to the attention-based EfficientNet-B1 model since it offered the best accuracy. It correctly predicts 121 out of 180 females as females, obtaining a 75.22% successrate. However, it misses predicting 59 females as males. With a 68.88% success rate, our technique properly predicts 106 out of 180 as males. However, it incorrectly determines 74 men to be female.

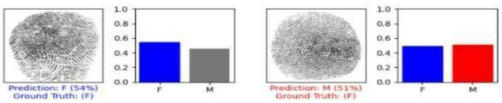

Figure 7: *Visualization examples of the Inception-V3 model on the Test dataset.*

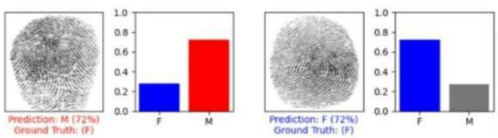

Figure 8: *Visualization examples of ResNet-101 model on Test dataset.*

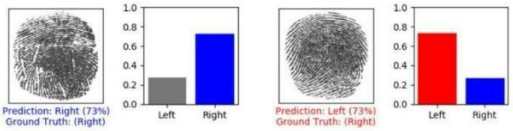

Figure 9: *Visualization examples of the EfficientNet-B1 model with attention mechanism on the Test dataset.*

Inception-V3, EfficientNet-B1, and ResNet-101 Visual representations on testing datasets are shown in Figures 7, 8 & 9. Correct and erroneous predictions are represented by the colors blue and red, respectively. Six images have been accurately categorized, with a prediction accuracy ranging from 67% to 73%. However, three images have been incorrectly identified, with a false prediction accuracy ranging from 53% to 72%.

Discussion

A significant quantity of training data is needed for the deep learning approach, which is an image-based feature extraction technique, to estimate gender from fingerprint photos. Stating by literature, a higher level of prediction accuracy can be attained with more training data. The variety of fingerprint images seeks to make the prediction more widely applicable. Due to the small number of finger print images, all of them are placed in the testing set; the remaining images are placed in the training and validation sets.

The results show that the ResNet-101 design performs better than its competitors, with an amazing 98.15% classification accuracy. In addition to highlighting the potential of deep learning for gender classification from fingerprints, this study highlights the implications of this technology for improving current biometric identity systems. Our findings open the door for further advancements in the incorporation of gender identification capabilities into biometric frameworks, which will ultimately lead to more reliable and adaptable identification systems as the field of biometric technology continues to change.

V.CONCLUSION & FUTURE WORK

In this paper, we used three cutting-edge models to propose a deep learning method for gender classification from fingerprint images: Inception-V3, ResNet-101, and an upgraded EfficientNet-B1 for attention. With training, validation, and testing accuracies of 96.15%, 93.56%, and 90.55%, respectively, our findings show that the attention-based EfficientNet-B1 model performed the best. By doing away with the need for laborious pre-processing and human feature extraction, this method demonstrates the effectiveness of automated methods in biometric applications. The results highlight how deep learning may be used to increase the

accuracy of gender categorization using fingerprint data, successfully resolving issues with dataset constraints and fingerprint quality. Overall, by showing that incorporating deep learning techniques may greatly improve the accuracy and efficiency of gender categorization, especially in forensic and security scenarios, this work advances biometric identification systems To further improve classification performance and broaden the applicability of these methods, future studies could concentrate on additional model improvements and investigate the use of multimodal biometric data.

Abstract. This paper introduces an AI-driven dual-drone SAR system for effective disaster response. The main drone mounted with thermal cameras, LiDAR, and YOLOv8-based detection, conducts real-time mapping and victim localization, including under debris. After detection, the secondary drone automatically flies to the location, employing Remote Photoplethysmography(rPPG) sensor Ultra-Wideband(UWB) radar sensor to monitor vital signs and differentiate survivors from fatalities. An ad hoc mesh network provides real-time data transfer, whereas a cloud database stores mission data for future analysis. With multi-sensor fusion, AI-driven detection, and reliable networking, the system reduces rescue time and survival rates during SAR missions.

Keyword. SAR, UAV for SAR, Real time victim detection, Rescue, Drone, search and rescue, 3D modelling, location mapping

I.INTRODUCTION

Natural disasters and building collapse present monolithic challenges for search-and-rescue (SAR) activities, hindering the identification and rescue of survivors with unfavorable conditions, restricted accessibility, and minimal visibility. Against these challenges, this paper advises Sky Guardians, an artificial intelligence (AI)-based dual-drone SAR platform to enhance victim identification, prognosis of survivor health, and real-time operational guidance. With a fusion of advanced drones, multi-sensor integration, strong communications networks, and cloud storage, this system gives an end-to-end solution for augmenting disaster response and delivering the highest possible survival rates.

The system consists of two specialized UAVs flying in formation. The lead aircraft, equipped with LiDAR and thermal imaging cameras, performs high-resolution 3D mapping and records human heat signatures, even in rubble or at night. On detecting a survivor, the second drone proceeds to where it has detected the survivor and takes vital signs using fusion of remote photoplethysmography(rPPG) and Ultra-Wideband(UWB) radar sensor that may aid in the identification of survivors over corpses.

To enable effective communication, the drones employ a UAV-to-UAV mesh network that delivers real-time information to a command center system irrespective of any external infrastructure. All that is obtained, victim positions, thermal imagery, heart rates, and weather, are displayed in real-time geospatial dashboarding through laptops, tablets, or any other smart device. This organic user interface provides real-time accurate survivor location and health information to rescue troops, allowing instantaneous, knowledge-based decision-making and optimal resource optimization. Meanwhile, all mission data are encrypted inside a cloud-based storage system for post-operation review, future disaster preparedness planning, and AI-optimized improvement.

Operationally, the master drone remotely surveys the affected area of disaster, identifies survivors, and alerts the secondary drone, which identifies survivor status. The information is communicated wirelessly throughout the mesh network, providing real-time situational awareness to operators of rescue. Through the integration of advanced sensor technology, artificial intelligence-based sensor detection, and secure communications networks, the system reduces response time considerably, improves detection accuracy, and maximizes SAR mission effectiveness

II.RELATED WORKS

Search and Rescue (SAR) operations utilize Unmanned Aerial Vehicles (UAVs) to support the efficiency of disaster relief missions by providing real-time mapping, survivor location, and situational awareness. SAR methods based on UAVs have been experimented with, but there are concerns for depth perception, assessment of the health condition of the survivor, and communication availability.

Lyu et al., (2023) [1] documented the application of UAVs in SAR, including real-time mapping and navigation. Even though their work is not a tutorial on multi-sensor fusion for enhancing detection accuracy, that would be an obligatory contribution.

Redmon et al. (2016) [2] developed YOLO, a popular real-time object detection system, which has been used heavily in SAR operations.

Rajeswari et al., 2023) [3], advancements in machine learning, such as semi-supervised regression using Generative Adversarial Networks (GANs) offer potential for improving SAR models by enhancing the training of detection algorithms with limited labeled data. This technique could be leveraged to refine survivor classification by training AI models on both labeled and unlabeled datasets, improving generalization in complex disaster environments.

Yeom (2024) [4] integrated UAV-based SAR and thermal imagery, which was actually very helpful in poor weather. All of that aside, all of these systems use large picture 2D image-based detection without depth perception to localize. Sensor fusion has been used to make the SAR more efficient.

Lohani & Ghosh (2017) [5] surveyed LiDAR-based 3D mapping, which can be efficient for terrain discovery but inefficient for survivor detection.

Sharma et al., (2024) [7], discussing ad hoc networking, real-time communication in SAR, or cloud-based data transfer. Specifically, it can support claims related to low-latency wireless communication and 5G-enabled real-time data transfer in UAV-based SAR missions.

Tariq et al. (2018) [6] proposed DronAID, which utilized deep learning and multi-sensor fusion for human detection. Similarly, Abbas et al. (2024) [11] proposed a UAV detection model based on a neural network. But these articles discuss detection models without referring to real-time survivor condition evaluation.

Mahavaishnavi et al. (2024) [8], in disaster scenarios - real-time data transmission and resource optimization are crucial for efficient SAR operations propose a dynamic resource allocation strategy in IoT-Fog architectures, leveraging differential services and adaptive QoS models to ensure efficient and reliable communication, which aligns with our ad hoc mesh network approach.

Q. Li et al., (2021) [10] proposes a UWB radar sensor-based, contactless vital sign monitoring system using edge computing and cloud infrastructure for real-time health tracking and emergency response. Experimental results show high accuracy in heart and respiratory rate detection,.

Sharma et al., (2024) [7] areas affected by disaster usually suffer from communication breakdown, making real-time information exchange difficult. To counter this, the system utilizes an ad hoc mesh network that enables uninterrupted UAV-to-UAV and UAV-to-Ground communication without relying on external infrastructure. The implementation of low-latency and high-reliability wireless communication, particularly leveraging advancements in 5G and beyond, significantly enhances real-time data transmission in disaster zones.

Furthermore, a recent publication on autonomous vehicle LiDAR and thermal infrared sensor fusion [10] was used to support enhanced object detection in various conditions, justifying the fusion of LiDAR and thermal for SAR-based UAV.

Fig. 1: comparison between existing and proposed project

A.Proposed solution

The envisioned AI-based dual-drone SAR system combines LiDAR, thermal imaging, rPPG, and UWB radar for effective victim detection and evaluation. The master drone conducts real-time mapping and survivor location, while the slave drone analyzes vital signs and biochemical parameters to differentiate survivors from the dead. An ad hoc mesh network provides real-time UAV-to-UAV and UAV-to-ground communication, with all information retained within a cloud-based system for rapid decision-making. This method improves detection accuracy, minimizes response time, and maximizes rescue operations.

III.LITERATURE SURVEY

The convergence of computer vision, sensors, LiDAR-based 3D mapping, network technology, and AI has hugely transformed search and rescue (SAR) operations to make the process quicker and more efficient. Huge amounts of research have gone into the usage of AI-supported Unmanned Aerial Vehicles (UAVs) for SAR, including their capability of flying automatically above disaster areas, locating survivors, and scanning risky terrain in 3D.

Lyu et al. (2023) [1] carried out an in-depth survey of UAV utilization in SAR, citing their capability to offer real-time mapping and survivor identification. Of the extensively researched object detection models, You Only Look Once (YOLO) has been proven to be real-time effective in survivor detection from RGB and thermal images. Redmon et al. (2016) [2] proposed YOLO as an integrated object detection model highly tailored for swift disaster response. Yeom (2024) [4] supplemented this with integrating thermal image following into UAV-based SAR and established that deep learning models combined with UAV-based thermal imaging highly boost detection accuracy in low-visibility situations.

Aside from object detection, LiDAR technology has been extensively researched for 3D terrain reconstruction and structural evaluation in case of a disaster. Lohani & Ghosh (2017) [5] surveyed airborne LiDAR systems, highlighting their ability to deliver high-resolution spatial data for navigation and infrastructure evaluation. LiDAR itself cannot detect the presence of humans, and hence sensor fusion becomes a crucial factor for enhancing detection accuracy. J.D.Choi et al. (2021) [12] developed a sensor fusion platform of thermal infrared cameras and LiDAR and illustrated enhanced object detection and depth estimation in autonomous cars.

SAR-oriented UAV platforms like DronAID (Tariq et al., 2018) [9] and DROPEX (Q. Li et al., 2021) [10] designed for real-time, contactless monitoring of vital signs using radar sensors, enabling efficient telehealth and emergency response, whereas Abbas et al. (2024) [11] designed human recognition via UAV-aided systems using neural networks. Nonetheless, these systems do not have real-time survivor evaluation capabilities, e.g., vital sign measurement and biochemical sensing, to select the priority of rescue operations. Our work is different from prior SAR systems in including YOLOv8 for object detection, fusion of rPPG and UWB radar for the measurement of heart rate, for a better evaluation of survivor conditions prior to launching the rescue.

One of the biggest challenges to SAR operations is real-time transmission of data, especially in disaster-affected areas where conventional communication networks are normally not available. Some networking methods for ensuring free communication among UAVs and ground stations have been studied by previous research. In contrast to conventional internet-oriented communication protocols like WebRTC, our system uses ad hoc networks, which consist of a self-organizing, decentralized form of communication network that enables the UAVs to communicate independently from a central network. Ad hoc networks have also been extensively investigated for disaster rescue purposes and exhibited strong resilience to build connectivity and uninterrupted data flow from the UAVs to the rescue teams.

IV.METHODOLOGY

Dual-drone SAR system utilizing AI and multi-sensor fusion proposed to improve victim detection, condition evaluation, and real-time communication during disaster. The system comprises multi-sensor fusion, AI object detection, and ad hoc networking. It enables efficient search and rescue with minimal human participation.

A. Primary Drone – Multi-Sensor Data Acquisition

The first unmanned aerial vehicle (UAV) and the main data collection platform of the system is provided with the vertically integrated LiDAR that is mounted with the thermal imaging sensors. The configuration of the system allows for the simultaneous multi-modal scan of the affected area. The LiDAR sensor is based on laser ranging and thus, it allows to create the three-dimensional high-resolution representation of the environment, mapping the terrain as well as the debris and the structural features with the high spatial accuracy. The thermal imaging sensor captures the infrared emission and can detect the heat signatures that are characteristic for the

human presence. The data is collected in terms of the same geospatial coordinates, so the structural context is provided by the LiDAR data, while the thermal imaging data help to identify the potential survivors. The collected data is stored in the different repositories and is further processed and analyzed in the workflow process.

B.Data Fusion and Human Detection via YOLOv8

Now, data is ingested with multi-sensor data collected by the primary UAV before human detection. A data fusion algorithmal process then fuses the LiDAR dimensional map data with the thermal imagery to create a unified dataset reflecting both the structural context and the infrared signatures. The fused dataset is then inputted to YOLOv8, a state-of-the-art CNN model for object detection. Leveraging the power of its pre-trained weights, YOLOv8 process the input data and identifies whether there are human in the disaster environment, using the new dataset and the enhanced feature representations to increase the accuracy and reliability of survivor detection beyond single modality thermal detection with greater robustness to environmental noise and occlusion.

C.3D Mapping and Data Relay to Rescue Operations

Human identification, based on the fused LiDAR-thermal dataset, the main UAV develops a detailed 3D environmental map exclusively according to the LiDAR sensor data. This map accurately represents the disaster terrain and its structural features and is used as a spatial framework. The accurate locations of humans, which have been identified in 'B' with the help of the integrated LiDAR-thermal analysis, are superimposed on this LiDAR-based 3D model. The exact geolocation of humans is carried out when the coordinates of humans, whose positions have already been identified with the help of the LiDAR-thermal integrated analysis, are superimposed to this LiDAR-derived 3D model.This mapped data, including the coordinates of the civilian survivors, is sent to the rescue coordination center in real time by a high-speed ad-hoc wireless network, the use of such communication provides the opportunity to deliver real-time actionable information, which facilitates the immediate implementation of search and rescue protocols.

D. Secondary UAV – Vital Signs Assessment

Survivor geolocation is sent in real time to RCC with the letter C, which transmits information to the secondary UAV. Further on, the second UAV flies to the assigned location of the disaster equipped with ultra wideband (UWB) technology for location tracking with high accuracy, as well as with remote photoplethysmography (rPPG) technology for non-invasive measurement of vital signs, including heart and respiratory rates. The UWB system lets the second UAV to navigate to the required location with high precision as it is specified in the 3D map, while the rPPG system assesses the condition of the survivor by their vital signs in an optical manner, such as the color of the skin. The sensor fusion process combines data of UWB location positioning and rPPG vital signs measurement and finally, data about the status of the individual (dead or alive), which significantly increases the system's robustness when it comes to prioritizing the search and rescue procedure.

E. Geospatial Dashboard and Unique Identification

Geospatial dashboard is designed that actually visualizes the data in real time and indicates the locations of the survivors and their vital signs accordingly. The interface combines the coordinates of the person with the metrics of their health, which provides full information for the rescue team. Moreover, each identified person is assigned an individual barcode that combines his or her exact location and health, which greatly facilitates the subsequent search and identification of the person, allowing for the rescue team to react as quickly as possible in the event of a disaster.

V.WORKFLOW

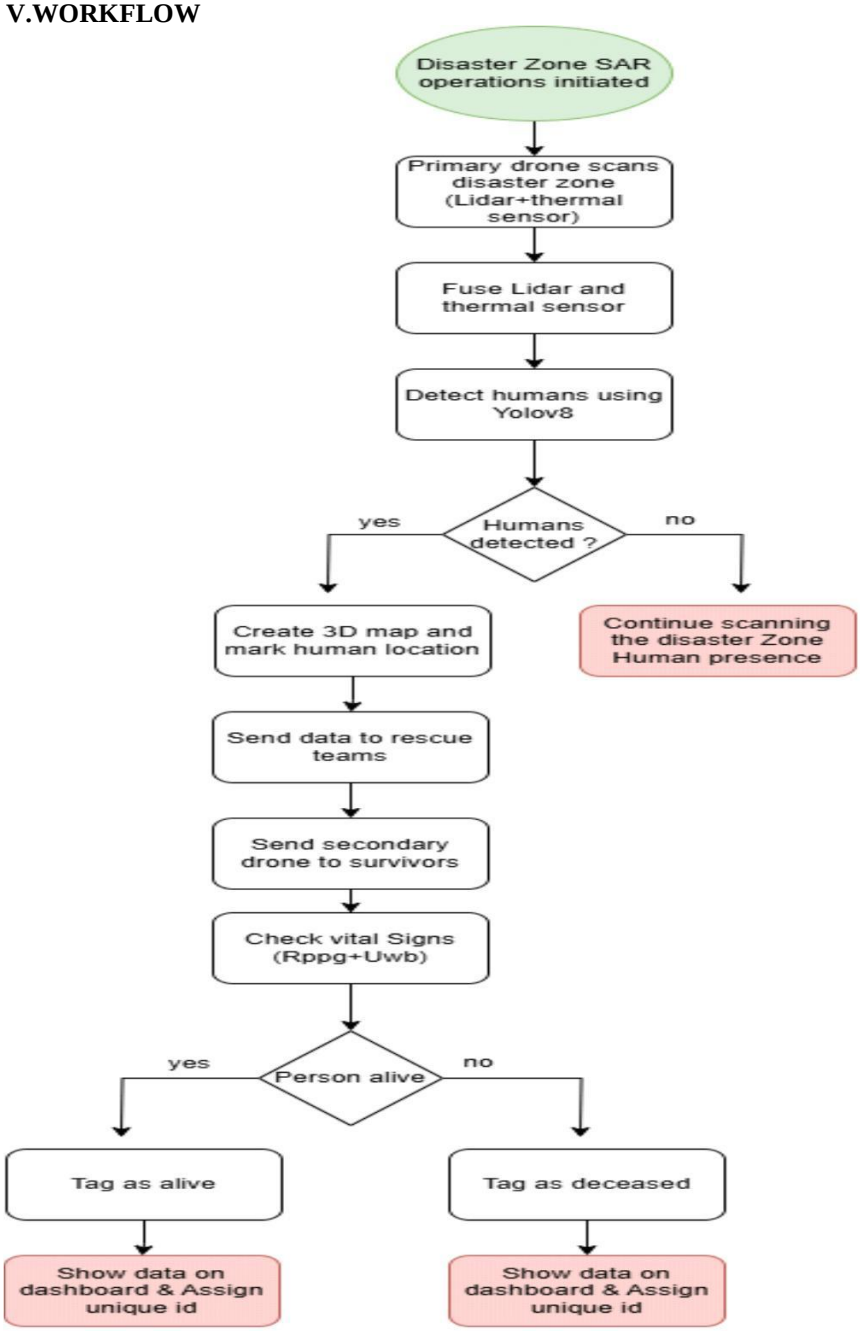

Fig 2: workflow of Sky Guardians

VI.ARCHITECTURE

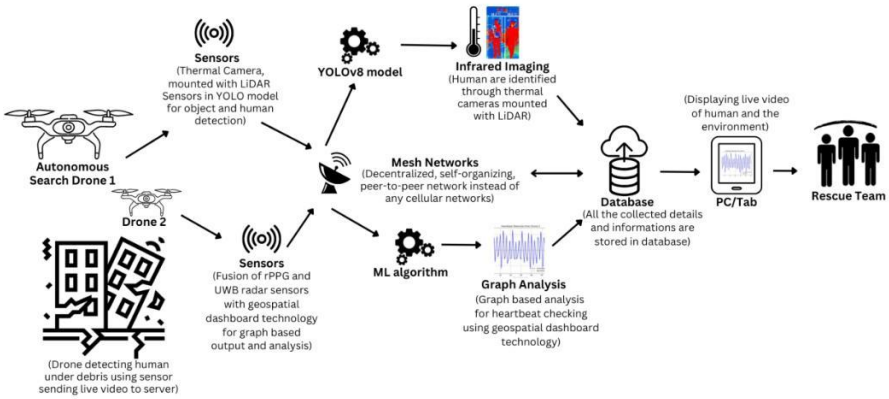

Fig.3: Sky Guardians architecture

VII.RESULT

The AI-based dual-drone SAR system, Sky Guardians, consolidates LiDAR, thermal, YOLOv8 object detection, rPPG, and UWB radar to achieve maximum survivor detection and rescue effectiveness. Through experimental evidence and theoretical simulation of the geospatial dashboard and YOLOv8, the system achieves maximum real-time object detection and visualization. Together, LiDAR and YOLOv8 will revolutionize the detection accuracy by combining accurate 3D spatial perception with rapid object detection. While YOLOv8 performs better with real-time human detection, LiDAR provides depth sensing and can therefore detect victims in dim lighting. Besides, rPPG+UWB radar combination enhances survivor screening to a level where non-touch vital sign monitoring and biochemical monitoring enable survivors to be discriminated from corpses and remove false alarms and increase the efficiency of the rescue ordering system.

The system also employs an ad hoc mesh network to establish UAV-to-UAV and UAV-to-ground wireless communications without errors in disaster-hit villages that do not have or do not have enough conventional infrastructure. Cloud-based geospatial dashboard experimentally validated offers real-time visualization of information for immediate access of survivors' locations and health status at the command of rescue teams for quick decision-making. Although the entire system is not yet applied in actual SAR operations, the YOLOv8 model and experimentally tested dashboard demonstrate that the system is able to process and provide important survivor information efficiently. Real-world testing for LiDAR-based mapping, rPPG, UWB radar integration, and UAV autonomous flight will be addressed in future works to improve detection accuracy, system performance, and response time optimization for effective SAR operations in mass disaster cases.

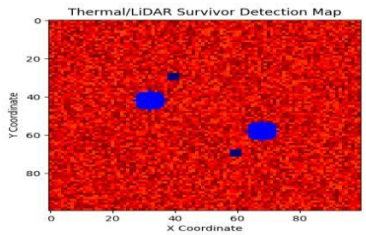

Fig. 4 illustrates Drone 1's localization of a 100x100 pixel map, thermal image (blue: 0–50, red: 255 units) and LiDAR height. Actual survivor locations at (30, 40) and (70, 60) under 4–5m rubble precisely match AI estimates at (32, 42) and (68, 58), demonstrating correct localization despite rubble.

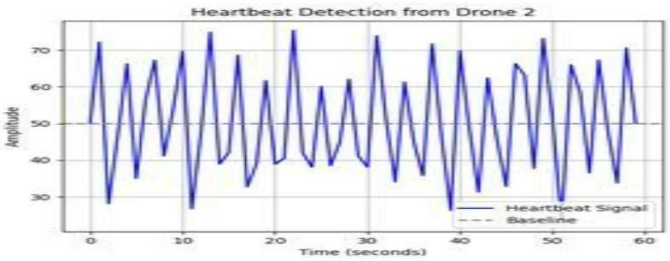

Fig. 5 shows Drone 2's 60-second pulse measurement, graphing amplitude (0–100 units) against time with an 80 bpm waveform riding about a 50-unit baseline. The 70-unit peaks, the 30-unit troughs, with ±5-unit noise, verify a survivor's pulse and illustrate accurate measurement of health to inform rescue triage.

```
from sklearn.metrics import precision_score, recall_score, f1_score

# Sample data
y_true = [1, 1, 0, 0]  # Ground truth: 2 survivors, 2 empty
y_pred = [1, 1, 0, 1]  # Predictions: 3 detected, 1 wrong

# Calculate metrics
precision = precision_score(y_true, y_pred)  # Correct detections / Total detections
recall = recall_score(y_true, y_pred)        # Correct detections / Total survivors
f1 = f1_score(y_true, y_pred)                # Harmonic mean of precision and recall

# Print results
print(f"Precision: {precision:.2f} (Correct detections out of all detections)")
print(f"Recall: {recall:.2f} (Correct detections out of all survivors)")
print(f"F1-Score: {f1:.2f} (Balanced accuracy)")

# Optional: Save to a text file
with open("accuracy_scores.txt", "w") as f:
    f.write(f"Precision: {precision:.2f}\nRecall: {recall:.2f}\nF1-Score: {f1:.2f}")
```

```
Precision: 0.67 (Correct detections out of all detections)
Recall: 1.00 (Correct detections out of all survivors)
F1-Score: 0.80 (Balanced accuracy)
```

Fig. 6 presents four test case precision measurements with Precision (0.67), Recall (1.00), and F1-Score (0.80). These indicate high survivor detection sensitivity (all true positives) with moderate false positives, confirming the system's effectiveness in SAR operations

VIII.CONCLUSION

The Sky Guardians SAR system based on two drones transforms earthquake disaster response by bringing together LiDAR, thermal imaging, and life sign detection to locate additional survivors and determine their status. Real-time system data synchronization is achieved via UAV-to-UAV communication, with actionable insight delivered to rescue personnel through the geospatial dashboard for efficient decision-making. Ad hoc networking and cloud storage usage improves data reliability and futurizing, making rescue organization efficient in less-capable networks. The system minimizes response time, enhances detection accuracy, and maximizes survival rate through AI-based multi-sensor fusion, real-time network operation, and self-navigating UAV mission, establishing a new standard for SAR efficiency in rescue relief.

IX.FUTURE ENCHANCEMENT

Development for the future for the Sky Guardians dual-drone SAR system should focus on better UAV-to-UAV coordination utilizing advanced swarm intelligence and AI for drones to have the ability to make autonomous, real-time choices without human control. Multimodal sensor fusion, including hyperspectral imaging and radar, may be used for enhanced victim detection in heavily cluttered environments as a means to further enhance the accuracy of the rescue. The geospatial dashboard can be enhanced with artificial intelligence-based predictive analytics to help the rescue teams prioritize the survivors depending on their existing health condition and risk of exposure. Edge computing on the drones will enable data processing on the ground, hence less reliance on cloud processing and resulting in quicker decision-making during crisis situations. Future enhancement can also be directed towards scalability with the coordination of multi-drones to respond over large disaster regions in a more efficient manner. These technological developments will also minimize response time, improve detection accuracy, and overall SAR capacity, making Sky Guardians a next-generation solution for large scale disaster response.

Abstract— This research article presents innovative solutions for assistive technologies that combine Amazon Alexa with two-way accessibility for deaf and mute people. By using real-time hand gesture recognition and adaptive visual feedback, system gestures are captured via video input,converted to visual representation and hand gestures side by side and provide context-related answers via Alexa. By combining text with synchronized gesture animation, dual output rendering improves communication clarity. The solution bridges communication asymmetries while maintaining operational rigor. Stakeholder alignment confirms its capacity to empower deaf and mute communities in technological engagement.

Keywords— Assistive technologies, Amazon Alexa, Deaf and mute, Hand gesture recognition, Visual feedback, Gesture animation, Communication clarity, Accessibility, Empowerment, Technology.

INTRODUCTION

AlexaSign Sync represents an assistive technology break through,leveraging Amazon's Alexa(first launched in 2014)to establish bidirectional Communication channels for deaf or mute individuals. Hand gesture recognition serves as the system's core input method, enabling sign language interpretation and custom gesture integration. Capture occurs through camera/depth sensor arrays,with processing hanby hine learning architectures including Convolutional Neural Networks (CNNs) for spatial pattern and Long Short-Term Memory (LSTM) networks for temporal sequencing..

These models undergo rigorous training on comprehensive sign language datasets to optimize recognition accuracy and adaptive performance. Gesture translation initiates dual-output. A synchronized video interface displays users' hand movements adjacent to contextual interpretations, while Alexa's voice synthesis converts gestures into audible speech. This multimodal approach – combining visual confirmation with real-time audio output - maintains clarity while fostering stakeholder alignment. AlexaSign Sync could enable communication between devices, allowing deaf or mute users to sign with a camera-enabled Alexa device, to act as an interpreter, providing translated context on the screen.

LITERATURE SURVEY

Sign Language Communication Gap and Deep Learning Solutions Sign language is crucial for millions of deaf individuals worldwide, but a significant communication gap exists between sign language users and non-sign language users. Deep learning has been applied to bridge this gap in three main areas:

Sign Language Recognition (SLR):
Identifying and interpreting sign gestures.

Sign Language Translation (SLT):
Converting gestures intomeaningful text or speech.

Sign Language Video Generation:
Generating sign language videos from text or speech using AI avatars.

Sign Language Recognition (SLR):

SLR involves recognizing hand movements, facial expressions, and body gestures. Traditional recognition systems, relying on methods like Histogram-Oriented Gradient (HOG) and Scale-Invariant Feature Transform (SIFT), were limited by manual feature selection and were sensitive to background and lighting changes. Deep learning has significantly improved recognition accuracy and scalability.

Convolutional Neural Networks (CNNs):

Useful for recognizing static signs, such as the ASL alphabet. Koller et al. (2019) demonstrated CNNs' effectiveness in isolated sign recognition.

Recurrent Neural Networks (RNNs):

Used to understand the temporal flow of gestures in continuous sign language, as demonstrated by Camgoz et al. (2020) who combined CNNs and RNNs for improved recognition.

SLR Transformers

These models better capture long-term dependencies in sign sequences and are increasingly used to improve recognition, even with complex body movements and facial expressions. Combining skeletal tracking and deep learning has further boosted accuracy.

Sign Language Translation (SLT):

SLT addresses the challenge of translating sign language gestures into text or speech. Sign language's unique grammatical structure makes this task complex. The breakthrough in this area came from Neural Machine Translation (NMT) models that leverage deep learning to enhance accuracy.

Sequence Models with Attention Mechanisms:

Camgoz et al. (2018)proposed sequence models that can analyze the entire sign sequence and context, improving grammatical and contextual accuracy.

Transformer-Based Models:

These models are used for better translation of sign sequences by considering individual gestures and the broader context, providing a more accurate translation.

Sign Language Video Generation:

After recognizing and translating sign language, the next step is generating sign language videos in real- time. AI-driven systems use.

Generative Adversarial Networks (GANs) and 3D modeling techniques- to create realistic sign language avatars.

GAN-Based Models:

Stoll et al. (2020) developed a system where human avatars sign words based on text input in real-time.

Human Modeling Techniques:

Tools like SMPL (Skinned Multi-Person Linear Model) and Neural Radiance Fields (NERFs) allow for realistic hand and facial movements, improving the quality and realism of generated videos.

Transformer-Based Drawing Models :

Saunders et al. (2021) enhanced video synthesis through transformer-based models, enabling more realistic and seamless sign language video generation.

METHODOLOGY

Dataset Description:

The dataset is derived from the Sign Language MNIST repository, this multi-class classification framework features 24 categories. A CSV-to-image conversion process was executed, with the full dataset downsized to optimize operational scalability. Comprising 27,455 grayscale images standardized at 28×28 pixels, the resource aligns letters A-Z to discrete classes. Notably, the letters J and Z require motion-dependent recognition and have been strategically excluded. All visual assets are stored in JPEG format, while the test subset contains 7,172 images. Through collaborative contribution channels, hand gesture data was initially captured from multiple contributors before augmentation via resizing techniques and multifilter applications

Data processing:

It consists of three key steps to recognize hand gestures with visualfeedback for comprehensive communication in the deaf and silent community: pre-processing, data expansion, model training. Enhanced technologies such as improved robustness models, such as rotation, inversion, brightness adaptation, and adding noise. Model training uses deep learning architectures such as CNNS (reset, mobile set, etc.) and pause-based models, and data is split into training, validation, and test sets. Optimization is based on category crosshead pole losses and optimizers with regularization techniques such as dropouts and transfer learning to improve accuracy. The final system provides visual feedback via text ads, avatars, haptic feedback, or AR-o overlays to ensure accessibility and inclusiveness.

Image Recoginition:

Image recognition is a subfield of computer vision and artificial intelligence (AI) that focuses on identifying and interpreting objects, patterns and functions in digital images and videos. Image recognition methodologies typically involve several important steps using extended algorithms, machine learning (ML), and deep learning (DL) techniques. This image reconstruction involves collecting and storage of image format data to perform the Release task. Collected handle photos were collected or processed to perform tasks after the training was processed. CNN (Folding Network) can learn to recognize edges, shapes,and hand patterns.The power of the model is evaluated using metrics such as accuracy and recall. After training, this model is provided on edge devices or cloud platforms for real applications with steps such as noise reduction and multimodal integration to improve returns and processing performance. This method supports frameworks such as Tensor flow, Pytorch,OpenCV, and other such that it allows for accurate interpretation of visual data.

CNN(Convolutional neural network):

Folding Network (CNN) is a deep learning model specially developed for image detection and processing. It is a feature that is automatically extracted from several levels of images, reducing the selection of manual functions. The process begins with an input image passing through a series of folding layers where a filter (kernel) scans the image to recognize patterns such as edges, textures, and shapes. After feature extraction,the image is flattened and fed into fully connected layers, where the extracted patterns are combined and analyzed to make a prediction. At the final level, we often use the SoftMax function. The ability to automatically learn spatial hierarchies of functions can be very effective in identifying complex images patterns. Despite challenges such as higharithmetic requirements and sensitivity to controversial attacks,CNN remains the backbone of modern computer vision.

$$\text{output}_{x,y} = \sum_{w} \sum_{w} \text{input}_{(x+w)(y+w)} \cdot \text{filter}_{w,w} + \text{bias}$$

Where:

- B = input image (matrix of pixel values)
- C = convolution kernel (filter weights)
- d = bias term
- A = output feature map
- x,y = pixel position in the feature map
- w = index of the convolution filter

SVM (Support Vector Machine):

Image recognition using Support Vector Machine (SVM) is a surveillance learning approach in which algorithms classify images by finding the best hyperbell for different classes.This process involves extracting properties with properties with related properties such as edges, color histograms, or texture patterns using techniques such as scaling of histogram-oriented gradients (HOG) and invariant types . Includes: It starts. These extracted properties are converted into numerical vectors and fed to the SVM classifier. Optimization is achieved with the Lagrange multiplier and the Carush- Chicken-Tucker state (KKT). If the data is not linearly separable, use particle functions (e.g. polynomials, radial fundamental functions (RBFS) or S-like microsynthesis) to convert the data into a higher dimensional space that allows for linear separation applications.

$$f(y) = a^{T}y + c$$

Where:

- y is the feature vector,
- a is the weight vector,
- c is the bias term.

RNN(Recurrent neural network):

Process image-to-video conversion by learning the temporal dependencies between repeating neural networks (RNNS) frames. First, characteristic vectors from the input image are extracted using folding networks (CNNs) or other characteristic extraction methods. These properties serve as sequential inputs for RNNs that maintain hidden state recording past framework information. For each time step, the RNN updates the hidden state based on the previous status and current input, and the next frame is predicted in the sequence. Variants such as long short-term memory (LSTM) and gate recurrence units (Grus) contribute to overcoming the degree of use and maintaining long-term dependencies. The predicted frame can be improved for better quality in a generative controversial network (geese) or automobile. This iterative process allows you to generate smooth, coherent video sequences from static images

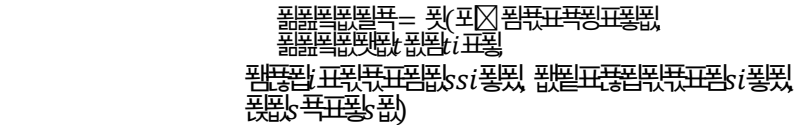
$$x_s = \text{필}(\text{필}_{x}x_{s-1} + \text{필}_{b}b_s + w_x)$$
$$t_s = h(\text{필}_{t}t_s + w_t)$$

Where:

- x_s - Hidden state at time step s representing learned temporal dependencies.
- b_s - Input at time s
- Z_x, Z_b , Z_s - Weight matrices for hidden states, inputs, and outputs.
- w_x , w_t - Bias terms.
- a (.) - Activation function
- t_s - Predicted output
- h(.)- Output activation function

NLP (Natural Language Process):

Task execution in Natural Language Processing (NLP) enables virtual assistants such as Alexa, Siri, and Google Assistant to efficiently interpret user commands and respond to user commands. This process begins with an input process. Intention detection then identifies the purpose of user requests using machine learning (ML), deep learning (DL) or regular systems, while Named Entity Recognition (NER) and Dependency Analysis are available in the location, such as location
Extract important details such as: Time or action. As soon as the intent and company is identified, the system interacts with external services via API calls, databases, or event control functions, invokes information and executes commands. After processing the request, Natural Language Generation.
(NLG) formulates the human answer, which is then converted from neural text to language with thehelp of a language (NTT) or displayed as text. Ultimately, the system improves over time through reinforcement learning (RL) and user feedback, increasing accuracy and efficiency.



$$\text{필}_{\text{퐥}} = \text{퐉퐦퐩퐥}(\text{퐥}) + F_{\text{퐩}} + \text{퐦퐩퐩퐥}(\text{퐩}) + \text{퐭퐩퐩} + \text{퐉퐦퐩퐩퐥}(\text{퐩})$$

Where:

- T_E → Task Execution
- NLU(I) → Natural Language Understanding on Input
- E → Entity Extraction
- A ^{E}PI(C) → API Call or Command Execution
- DM → Dialog Management
- NLG(O) → Natural Language Generation for Output.

Wake up Gesture

For deaf and quiet people, Alexa alarm process can be adapted using gesture recognition.Cameras or movement sensors are monitored continuously for predefined hand gestures or facial expressions. When recognized gestures such as waves and specific symbols are recognized, they process the AI-based model and convert them into digital commands. This command is sent for intent detection, similar to how Alexa handles spoken language. The system determines the user requests.Check the weather or control of the intelligent device. As soon as your intent is identified, Alexa generates an answer that is visually displayed on the screen, communicated by vibration feedback or that can send signals with intelligent lights. The interaction is seamless and ensures accessibility. If a follow-up response is expected, Alexa will remain active for a short period of time. AI continuously learns and improves recognition accuracy. This approach allows nonverbal users to interact effectively with Alexa without the need for language.

Where:

- Microphone = Always listening for input
- WakeDetection = AI model detects
- AudioProcessing = Converts speech to digital signals
- CloudProcessing = NLP & ML analyze intent
- Response = Alexa provides output

Generic Conghersarial Networks:

Generic Conghersarial Networks (Goose) uses two neural networks and distinguishing features to combine video frames of photographs. First, the generator shows static photographs and noise, creating many frames that predict movement and transformation. The discriminator evaluates these frames created for real video play to distinguish between actual and false sequences.Generators are continuously improved by minimizing the difference between the actual and generated frames.The temporal consistency module ensures smooth transitions between frames. Optical flow technologies or repeating networks (such as LSTM) can improve mobility prediction.

Controversial training improves videoism across several iterations. The loss function derives the generator and creates a realistic video sequence. After all, Gan creates high quality videos from one photo. This process is often used in animation, deeppo technology and video integration.

Where:

- V = Generated video sequence
- I = Input image
- z = Latent noise vector
- T = Motion transformation model ensuring temporal consistency

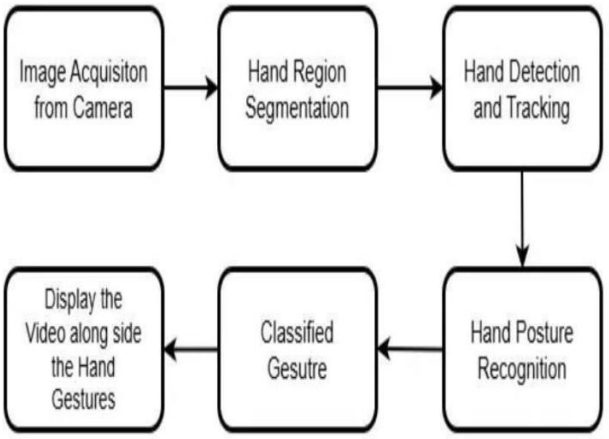
K-Nearest Neighbors:

K-Nearest Neighbors (KNN) is a simple but effective algorithm for image recognition based on similarity measurements. First, the image is converted into distinctive vectors using techniques such as pixel intensity, histograms, and deep learning beds. If a new image is provided for recognition, its characteristic vector is extracted. The algorithm calculates the distance (such as Euclidean distance) between the new image and all saved images in the data record. Kenest Pictures (Neighbors) are identified based on this distance. The majority election mechanism determines the class of input images based on the most common class of K-Neighbors. The photos are then sorted accordingly. The accuracy of the KNN depends on the K selection and the characteristic extraction method. KNN is not parametric and works well with small data records, but gradually works for large image databases.

$$d(p, q) = \sqrt{\sum_{i=1}^{n} (p_i - q_i)^2}$$

Where:

- p, q = Feature vectors of the input image and a dataset image
- n = Number of features
- $d(p, q)$ = Distance between the two image



MediaPipe:

MediaPipe is a powerful framework for processing real-time image and video data using machine learning models. For edge detection and connection, the input image is initially adopted, and preprocessing techniques such as grayscale transformation and normalization are used. Capture edges using folding networks or classic edge recognition algorithms .The framework identifies the most important edge points and improves them by filtering noise. Drap-based models analyze edge structure and continuity. The recognized edges are connected using contour tracking or diagram optimization algorithms. Mediapipe uses smoothing techniques to maintain a natural connection between the edges. The processed images will be displayed or sent for further use.Object recognition or feature extraction. Real-time optimization ensures fast and efficient edge connections on mobile devices. The result is a sophisticated, structured image with well-defined edges and smooth connections.

$$G = \sqrt{G_x^2 + G_y^2}$$

Where:

- G_x, G_y = Gradients in the x and y directions
- G= Edge intensity

Working of Alexa:

Alexa skills handle inquiries from users such as songs and show videos. This is combined with the interpretation of sign language to ensure access is made to the deaf and silent switching users when video is requested. The hand gestures used for interpretation can come from a sign language avatar that performs in addition to a video that translates audio content or from an actual hand gesture or animation that conveys the same message. This means that video content and hand gestures will be displayed side by side in the Echo Show. For example, if a user requests a music video, one side of the screen will display the music video, and the other side will display people who sign the text of the song in real time and who will understand the user better.

Combining of CNN and RNN:

1. **Role of CNN in Hand Gesture Recognition**

CNNs are predominantly employed for spatial feature extraction within hand gesture images or video frames. Proficiency is demonstrated in capturing localized patterns, edges, shapes, and textures, that prove essential for gesture recognition. Each frame from the input video or image undergoes processing by the CNN, enabling the extraction of high-level spatial features. A critical foundation for accurate interpretation.

Input: Sequential video frames or static images depicting hand gestures.

Output: Feature vectors (or feature maps) encapsulating spatial gesture data per frame.

2. Role of RNN in Hand Gesture Recognition

RNNs, specifically LSTM (Long Short-Term Memory) or GRU (Gated Recurrent Units), are leveraged to analyze temporal dependencies across gesture sequences. Dynamic gestures require motion analysis over time, a task addressed through the RNN's capacity to model sequential progression. Temporal coherence is thereby maintained.

Input: Feature vector sequences derived from CNN outputs, reflecting temporal gesture evolution.

Output: Predictive sequences or consolidated gesture classifications.

Integrating Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) into a hybrid architecture is a dynamic process that leverages the respective strengths of both paradigms to tackle hand gesture recognition challenges. Initially, the system utilizes the spatial analysis capabilities of CNNs for feature extraction. Each input video frame goes through the CNN, and resulting feature vectors or feature maps, compact representations of the frames' spatial traits, such as edges, shapes, and textures, are captured. Given these findings, we aim to distill essential visual information necessary for identifying unique hand gestures.

In the next step, temporal modeling, the RNN processes the sequence of feature vectors, modeling temporal relationships across frames to capture dynamic gestures unfolding progressively. Typically utilizing LSTM or GRU units to handle sequential input, this processing model effectively decouples dependencies between frames, assessing crucial hand movements essential for a particular gesture. After analyzing the sequence of frames, the RNN may generate predictions for each frame separately or for the complete gesture, offering rich context for action classification.

Driving toward actionable insights, the classifier assimilates data from the RNN, streamlines processing via a fully connected neural layer, and rounds off via the softmax activation function. Achieving strategic alignment, this intermeshed system precisely evaluates simultaneous information spatially and temporally. Consequently, applications capitalizing on this dynamic design benefit significantly, including those catering to hand gesture communication within hard-of-hearing and non-verbal communities.

Resultantly, fusion performance of spatial extraction, alongside the modeling strength lent by temporally gated frameworks bolsters integrated solutions deserving such tasks' accuracy demand. A potent harmony. Unprecedented robustness also, through the multiple dimension knowledge aggregation the arrangement delivers.

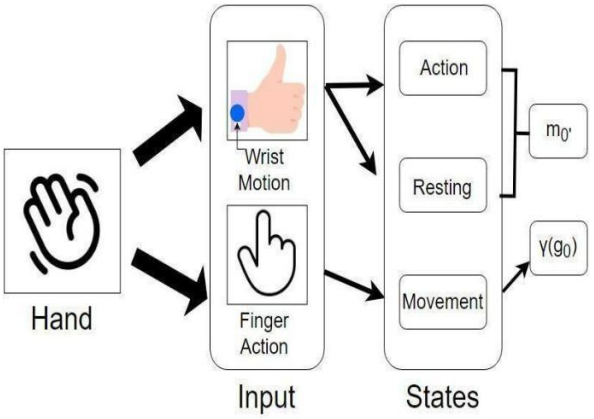
Hand Tracking:

1. Hand(Input Source):

The process initiation point is the hand, capable of executing movements or performing gestures.

2. Inputs (Wrist Motion & Finger Action):

Capturing wrist movement often leverages a sensor or camera,effectively documenting motion from the wrist. Detecting finger positions or gestures is also critical, encompassing various configurations such as an open palm, a clenched fist, or the pointing gesture.



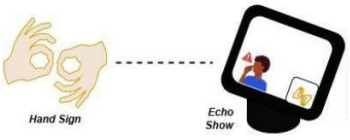
`3. ***States (Processing System):***

A corresponding active state is identified, leading to successful action execution. A critical insight: the action-initiated state.This underscores the idle state – characterized by insignificant movement or a neutral hand position denoted as 'Resting'. Conversely, the transient 'Movement' state implies hand activity detected without an action classification.

4. ***Outputs:***

The outputs correlate strongly with hand motion: An executed action, denoted as m_0', reflects this delicate interplay between gesture recognition and the processed outcome.

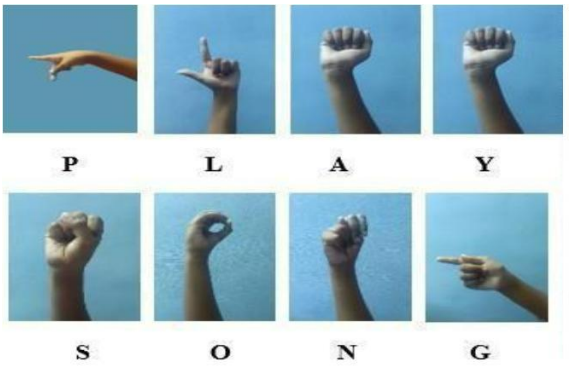
As a direct extension, γ(go) plausibly relates to a generated control signal aligning with an identified gesture, given specified parameters.



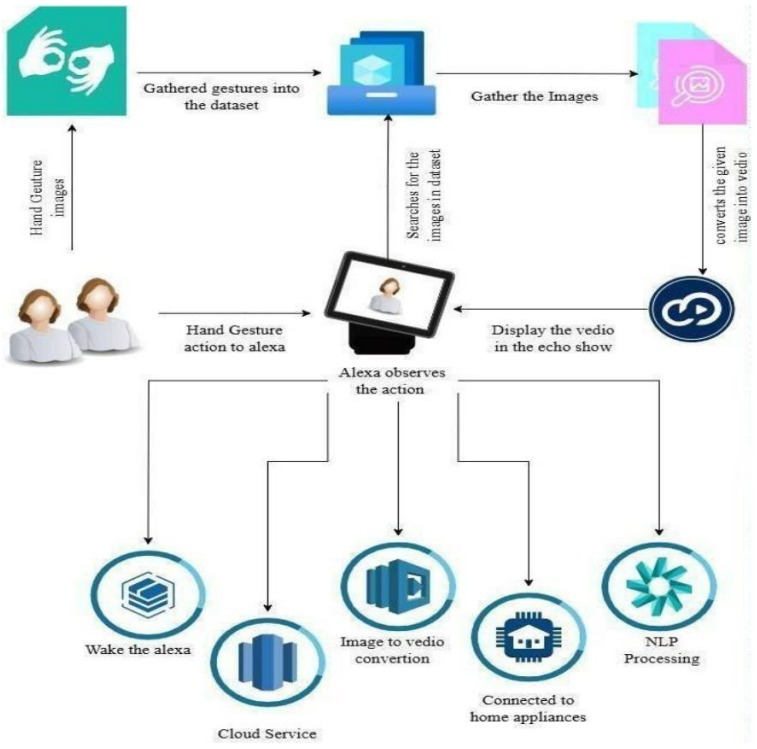
Optimization and Strategies:

To use hands recognition (HGR) and ** visual feedback * that helps communicate communities of deaf and mute, system optimization is necessary to make it fast and effective. Using simpler models, such as Mobilenet , helps to reduce load processing, while techniques such as pruning (removing unnecessary parts of the model) and quantization (reduces the model) to accelerate power without losing accuracy. Starting these models on Edge (such as smartphones or intelligent glasses) with special chips, such as Edgetp Google, allows the system to operate faster by processing gestures instead of relying to the Internet. In addition, adjusting how often the frames are processed, and smoothing recognition over time helps make the system more stable. Data Augmentation (change of training data to simulate different environments) and transmission learning ** (using knowledge from other models) help the system work well in different conditions. All these optimizations ensure that the system works smoothly and quickly for a real time communication.

Existing System:



There are emerging systems that combine Alexa with gesture recognition to aid people who are deaf or hard of hearing. These systems use technologies like motion sensors, cameras, or wearable devices to track hand gestures, which are then translated into commands Alexa can recognize. For example, gestures such as waves, displays or triggers, such as, turn on the light, play music, or adjust the temperature. Additionally, Sign Languages detection is another development area where AI- operated algorithms and special sensors can interpret sign language gestures and translate them into text or speech that Alexa can understand. Alexa does not support gesture control natives, but allows users to interact with voice assistants without speaking or listening.



American Sign Language:

Example:

Architecture Diagram:

Conclusion:

This system offers considerable benefits to hearing impaired communities by improving accessibility. In addition to the main content, you can enjoy videos such as listening to users with additional support for hand gesture interpretations. Easy understanding is improved, especially in videos that contain spoken language and complex information, as hand gestures make participation easier. Sign language support to fully understand the content. This way you can access the media and enjoy yourself

Abstract— Traditional personalized medicine is often expensive and inaccessible, limiting its global impact. This paper proposes **AI-COMPASS (Cost-Effective Optimized Medicine for Personalized Accessibility and Scalable Solutions**), an AI-driven framework that enhances treatment precision while ensuring affordability. By integrating **federated learning**, patient data remains secure while enabling collaborative AI training across hospitals. A novel **multi-omics deep learning model** analyzes **genomics, proteomics, and metabolomics** to predict optimal drug responses. Additionally**, Edge AI computing** enables real-time decision-making, reducing reliance on costly infrastructure**.** An **adaptive reinforcement learning mechanism** refines treatments dynamically**. AI-COMPASS enhances treatment accuracy, cost efficiency, and accessibility, making personalized medicine feasible** for diverse populations.

Keywords— ***AI-COMPASS, Personalized Medicine, Artificial Intelligence, Federated Learning, Multi-Omics, Edge AI, Reinforcement Learning, Cost-Effective Healthcare, Precision Treatment, Drug Response Optimization, Accessible Healthcare***

I. INTRODUCTION

In the **traditional** method of medicine, the diagnosis of the disease may not be accurate all the time. In some cases, it may even **increase** the **severity** of the disease due to the delayed diagnosis .In the proposed system ,the advanced technologies are incorporated with the laboratory equipment to detect the disease easily and also to prescribe appropriate drug for the individual patient. The late diagnosis has led to the severity of the disease. To overcome this kind of situation, the proposed system intend to incorporate advanced technologies like **Multi-omic deep learning, Edge AI, Federated learning, and Adaptive reinforcement learning** in the Laboratory to diagnose the disease or disorder at an earlier stage.

Any potent drug, it poses the risk of dangerous consequences in the case of over or under dosage. Warfarin is one of the most commonly used anticoagulants due to its effectiveness. It works in tandem with the VKORC1 gene, and its metabolism is dictated by the CYP2C9 gene. The presence of these factors along with other individuals' genetic uniqueness means that there will always be a different response to Warfarin alonWith the accompanying phonemics and the facts genetic factors. Therefore, the FDA has signaled a recommendation to alter their warfarin administration protocols by suggesting that dosing be controlled based on one's genetic information, specifically in regard to the variations of the VKORC1 and CYP2C9. Whether a patient is active or passive dosed affects their genetic features, which in return creates space for more precise therapeutic approaches to be created. A small portion of the government's spending on pharmaceuticals could help increase the scopes of clinical studies, without genetics being an exception to the rule of basic care.

The proposed system can also be used to prescribe the medicine to the individual based on their **genomic, proteomic, metabolomics, medical history and lifestyle.** Traditionally**,**Personalized medicine is a novel approach toward medicine because it allows a patient's genetic information, molecular traits, and lifestyle habits to dictate medical interventions, which ideally improves treatment effectiveness and side effects. However, the implementation of this medicine style is largely inhibited by high costs, data privacy concerns, and strong computational requirements. In order to address these issues, the AI-based frame-of-reference improvement Precision medicine **affordability** and accessibility, while
ensuring that it remains scalable has been developed by **AI-COMPASS** (Cost-Effective Optimized Medicine for Personalized Accessibility and Scalable Solutions). To obtain an effective AI implanted system for personalized medicine, the data is initially collected and preprocessed. The data is collected from various sources. The best model and training method is selected. The small scale dataset can be used for specific disease prediction.The medium scale dataset can be used for imaging.The large scale dataset can be used for federated learning across lab.Shallow models uses 10-100 epochs,Imaging of a genomic sequences uses 50-500 epochs
Learning rates very based on model complexity and training setup .Shallow model use 0.01-0.1,while Deep learning model use 0.0001-0.01.Federated learning use 0.001-0.01.

These components collectively constitute the basis of AI-COMPASS to improve personal medicine precision, cost, and accessibility via federated learning, multi-omics deep learning, and edge AI computing.

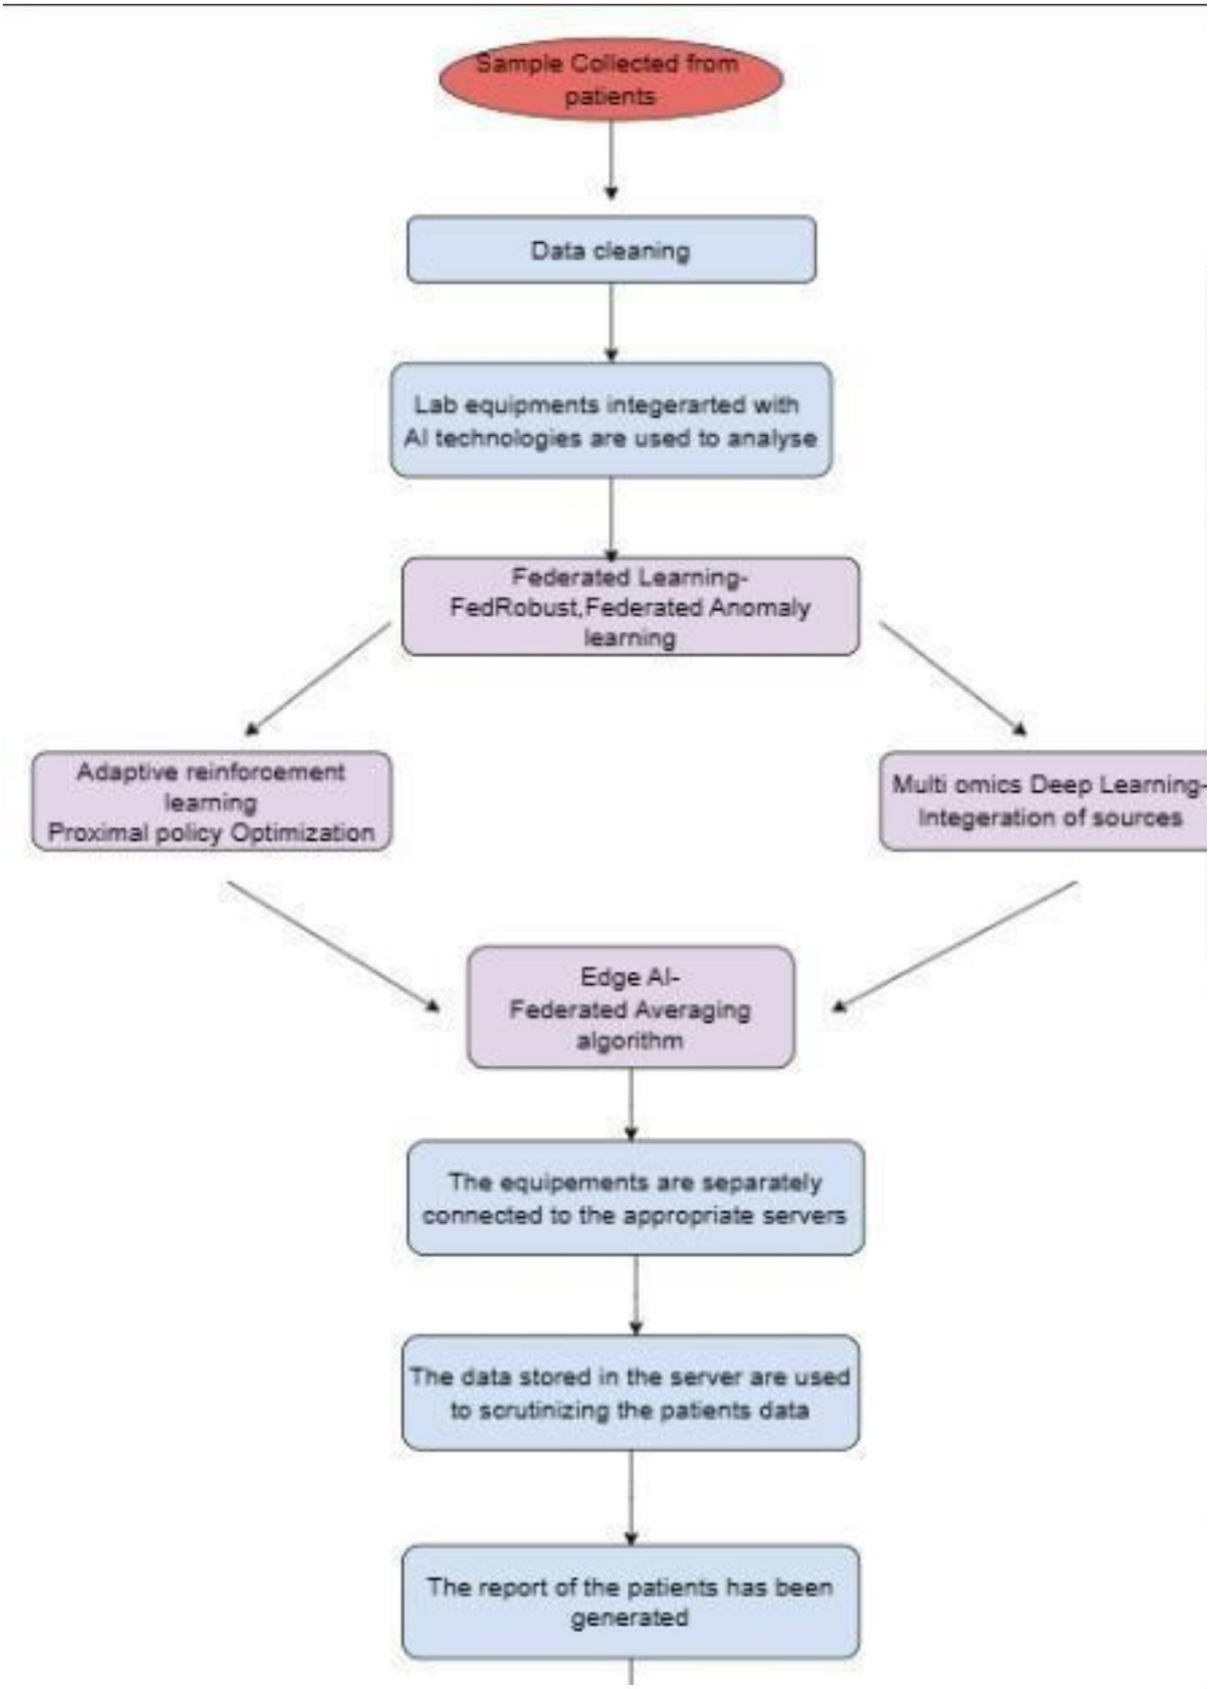
I. METHODOLOGY

2 .1 Federated Learning:

One of the big challenges for the AI based health care solution is to ensure data privacy, data security and regulatory compliance. Federated Learning (FL) is a **decentralized** AI training method which can allow different healthcare organizations to jointly train AI models without having to disclose privatepatient information.Unlike traditional approaches with centralized

data residing in one place, FL will allow institutions to undertake AI model training locally and communicate model updates with a central server, for instance, gradients or weights, thus ensuring the protection and security of data. This approach helps to enable AI-COMPASS to comply with various regulations like HIPAA, GDPR, etc. while reducing the chances of data breach.Moreover, FL encourages sharing of intelligence with hospitals, research facilities, and pharmaceutical companies to develop powerful AI models without the requirement of raw data exposure. AI-COMPASS employs.

2.2 Multi-Omics Deep Learning for Comprehensive Data Analysis:



Personalized medicine isn't treating patients, it's treating people. It's understanding what makes each person different—genes, biology, lifestyle—and applying that to create treatments tailored to them. Doctors can now dig deep into a patient's clinical and biological data to find out what's really going on with their health. AI-COMPASS is revolutionary software that makes that possible. It takes an enormous database of information—genomics (DNA and genetic mutations), transcriptomics (levels of gene expression), proteomics (what proteins do), metabolomics (metabolic changes), and clinical data (medical history, scans, and health records). By integrating all of those, AI-COMPASS builds an end-to-end picture of an individual's health, enabling doctors to find disease biomarkers, observe how diseases work at the molecular level, and detect very subtle changes in the body. That composite image delivers accurate diagnoses and treatments that are genuinely personalized.

What is especially strong about AI-COMPASS is that it harnesses cutting-edge artificial intelligence. Graph Neural Networks (GNNs) understand complex interaction between genes, proteins, and metabolic pathways, and Convolutional Neural Networks (CNNs) understand medical images to give diagnostic assistance. For time series data, i.e., for a patient's clinical history or biological signals, Recurrent Neural Networks (RNNs) and Transformers recognize patterns and trends. Autoencoders step in and compress huge databases to render key information available so the most precious insights can be gleaned. Based on these advances, AI-COMPASS can forecast the course of a disease, identify the most promising potential drug targets, and design regimens of therapy that are best matched to each patient's unique requirements. By capitalizing on the richness of multi-omics data and AI, AI-COMPASS is transforming individualized medicine and promising improved health and a brighter future for all.

2.3 Edge AI Computing for Real-Time, Cost-Effective Decision-Making:

A major challenge in personalized medicine is the cost and computation demands of the AI healthcare system, as it, in general, requires a high-performance computing (HPC) infrastructure. AI-COMPASS is solving this challenge through the implementation of Edge AI computing, allowing ML-powered models to run at the level of hospital dedicated servers, mobile health applications, and IoT-enabled (bio)sensors.Without the need for cloud processing, enabling real-time clinical decision-making for places with constraine resources.

The strategies like Model optimization, Model pruning, Knowledge Distillation, Edge AI chip, Microprocessor are used to attain Edge AI. The hardware devices in laboratories are connected to its respective servers rather than Cloud which is affordable for the labs with specific hardware devices.

Sample Collected from patients
Data cleaning
Lab equipments integerarted with AI technologies are used to analyse
Federated Learning- FedRobust,Federated Anomaly learning
Adaptive reinforcement learning Proximal policy Optimization
Multi omics Deep Learning- Integeration of sources
Edge AI- Federated Averaging algorithm
The equipements are separately connected to the appropriate servers
The data stored in the server are used to scrutinizing the patients data
The report of the patients has been generated

II. COMPARISON BETWEEN AI-COMPASS AND EXISTING SYSTEM:

BASIS	EXISTING SYSTEM	PROPOSED SYSTEM
ACCURACY	It completely relies on centralized models which are trained on limited datasets, which leads to lower accuracy in predicting.	Uses **FL** and **MULTI-OMICS DEEP LEARNING**, which allows various diverse data sources during preserving privacy, which tends to give higher accuracy and more personalized insights
SCALABILITY	The data are processed which struggles with large datasets, leading to hindrances.	**FL** enables training which is decentralized, it improves scalability across multiple IOT devices and healthcare institutions.
EFFICIENCY	Need large computational resources and cloud processing, which eventually leads to delays in real-time applications.	**EDGE AI** is used to process the data locally, which helps in reducing latency and makes the real-time decision-making efficient

TABLE:1

III. PROPOSED SYSTEM

The algorithms listed below are the most important components of the proposed system:

- **FedAvg (Federated Averaging) -** Federated learning.
- **Knowledge distillation-** Edge AI.
- **Graph Neural Networks –** Multi Omics Deep Learning.
- **Proximal Policy Optimization (PPO)-** Reinforcement learning.
- **Multi-Modal Deep Learning-** Multi-Omics Data Integration.

Data Classification	Source	Purpose
Genomics	Sequence DNA	Identifies the genetic markers for diabetes mellitus..
Proteomics	Hematological tests	Monitor proteins that act on insulin.
Metabolomics	Urine and blood samples	Manages glucose metabolism
Lifestyle Data	Mobile apps, smartwatches	Monitors diet, exercise, and sleep habits
Clinical Records	Hospital EHRs-Real-Time Glucose Monitoring	Reviews past interventions and their effectiveness..
Real-Time Blood Glucose Monitoring	CGMs (Continuous Glucose Monitors)	Offers instant blood glucose value for artificial intelligence analysis.

IV. KEY FEATURES:

1. Edge AI Computing Benefits In Personalized Medicine Reduced Latency: Processing everything at the Edge renders promptness within diagnosis and treatment suggestions absolutely free of the latencies normally incurred by cloud computing.

2. Cost-Effective: The AI-COMPASS benefits from the existing information system infrastructures and mobile devices for medical purposes and thus lessened reliance on expensive centralized data centers.

3. Improved Data Security: Data are processed on site, which significantly reduces exposure to data transfer, hence improving the degree of compliance with the most stringent HIPAA and GDPR standards.

4. Scalability: The system is tailor-fit for rural healthcare providers, telemedicine, and mobile health clinics hence increased accessibility.

AI-COMPASS deployed TinyML and quantized DNN frameworks by achieving the required accuracy outcomes but being computationally light for usage over low-power, resource-limited devices.

V. CASE STUDY

How AI-COMPASS Will Personalize Diabetes Treatment

AI-COMPASS will compare genomic, lifestyle, and clinical information to develop a personalized treatment strategy for every patient with diabetes. This is the way:

- Personalised Insulins and Medicines:

-AI will forecast the way a patient's body uses insulin
-Recommend optimal doses of insulin & drug regimens
-Identify drug resistance by genetic testing.

- Lifestyle and Dietary Guidelines:

-AI will track how different foods affect blood sugar.
-Provide customized diet recommendations based on metabolic reactions.
-Provide exercise guidelines to manage blood glucose levels

- Early Complication Detection:

-AI will forecast risks of complications (e.g., nerve complications, kidney injury)
- Suggest preventive measures before complications set in.

VI Conclusion

AI-Compass-Cost-effective Optimized Medicines for Personalized Accessibility and Scalable solutions-is a significant movement to increasing the affordability, accessibility, and efficiency of personalized medicine. This platform utilized the Federated learning, multi-omics deep learning, and Edge AI computation to securely collaborate AI models, totally analyze all data, and make decisions in real time to cover the major barriers created by exorbitantly charging and data security in precision medicine. Adding artificial intelligence approaches to personalized medicine can be expected to Islamic health, whereby cases of individualized treatment, early disease diagnosis, and best-choice drug selections will all become possible based on the optimized heterogeneous populations. Future researchers will seek to better model explainability, garner larger real-world validation studies, and increasingly streamline regulatory pipelines for approval toward more widespread clinical use. The affordable and scalable form of personalized medicine that becomes "democratized" will allow much of the population to benefit from the most innovative and upfront treatment strategies, improving patient outcomes while closing the gap between research breakthroughs and end-consumer practice .

ABSTRACT:

Mentoring makes it easier for people to learn from and share knowledge with one another. In the field of education, it frequently entails assigning young people to an older peer or adult volunteer who acts as a positive role model. Mentoring places more of an emphasis on fostering relationships, self-esteem, character, and resilience than standard teaching, which concentrates on academic abilities. One of the best examples of the apprentice model is academic mentoring, in which a professor guides a student with knowledge, advice, and support in both personal and academic domains. A person's professional identity and psychological adaptability are improved by this kind of mentoring. The system employs sophisticated facial recognition technology with face detection, vector representation, and Euclidean distance for face comparison in order to guarantee mentor authenticity and experience. Apart from facial recognition, the platform enables mentees to arrange meetings with mentors according to their availability, employing automated scheduling systems such as Google Calendar and Calendly. For smooth mentoring sessions, the website also offers services like file sharing, video conference, and chat.

INTRODUCTION:

The platform leverages AI-driven scheduling, secure video communication, and comprehensive feedback analytics to provide personalized, efficient, and continuously improving mentor-mentee interactions for skill development and professional growth. Individualized mentorship is crucial for skill improvement and professional growth in today's fast-paced, dynamic labour market. Through the use of cutting-edge technologies such as artificial intelligence (AI), machine learning, and automation, the proposed career mentorship platform aims to bridge the gap between experienced mentors and ambitious professionals. This platform ensures that candidates from diverse industries can readily establish connections with mentors, obtain tailored career support, and track their advancement. Its purpose is to increase the effectiveness of the mentoring process. The platform goes beyond traditional mentorship with features including an AI-driven mentor-mentee matching system, an automated calendar booking system, real-time communication tools, and advanced analytics to track skill progress. These characteristics offer a creative, practical, and responsive approach to meeting the unique needs of each mentor and mentee.

LITERATURE REVIEW:

D. C. E. Sinex et al. [1] The study explores the Pitt STRIVE mentor-mentee retreat at the University of Pittsburgh, highlighting its effectiveness in promoting cultural awareness, strengthening relationships, and fostering a supportive community for underrepresented graduate students. T. Nguyen et al. [2] The paper introduces an innovative IT mentorship system with two websites for mentor-mentee collaboration and administrative management, featuring face recognition for mentor verification, chat, video calls, and file sharing. J. Gadad et al. [3] The paper discusses the 2017 introduction of the Mentors In Thinkering Lab(MITRA) program at KLE Technological University, India, which provides peer mentoring to first-year engineering students to solve interdisciplinary design problems using mechatronic prototypes. S. Karthikeyan et al. [4] The android application aims to connect students with industry mentors and provide insights on career opportunities and workplace culture. It connects students with future coworkers and helps professionals find the best job opportunities. The app helps students make informed decisions about their future careers, reducing uncertainty and promoting success in the work place. S. Schaffel et al. [5] The study examines the mentor-mentee dynamic in military workforce modeling, comparing continuous deterministic and discrete stochastic simulations, focusing on career progression within hypothetical military occupations. M. Anderson et al. [6] USES is an online module aimed at improving mentor-

mentee relationships for Black CS graduate students, addressing stereotype threat and unconscious bias, and enhancing professional development. S. Arora et al. [7] This paper explores AI mentoring as a modern, round-the-clock alternative to traditional mentoring, highlighting its benefits and potential future possibilities. T. Kustova et al. [8] The study explores interbrain synchrony (IBS) between mentors and mentees in a naturalistic workplace, finding higher IBS in free communication and decreasing over time. N. H. Norhamidi et al. [9] The academic advisor at Kulliyyah of Engineering, International Islamic University Malaysia, proposes an online monitoring system for the mentor-mentee programme, focusing on mentees facing difficulties and utilizing PHP technology and MySQL for database management. I. Chiranmai et al. [10] During the Covid-19 pandemic, online coaching became popular, but network issues and remote areas hinder connections. Electronic mentoring (e-mentoring) offers a solution for mentors and mentees, allowing communication and tracking of academic progress. Future plans include incorporating artificial intelligence for better student growth. I. Y. Rassokhina et al. [11] The article explores the effectiveness of digital tools in mentoring undergraduates in project-based educational activities, focusing on horizontal peer-to-peer training and remote interaction. A. Medina-Quesada et al. [12] The Jaén School of Engineering introduces tutorial plans and mentoring programs as essential pillars for student development. The program involves teachers- tutors and student-mentors, promoting academic, personal, and professional competences. Supported by the Board Team and technical committee. J. Varghese and M. Mohaghegh et al. [13] This study explores the importance of mentorship relationships in the workplace, focusing on aligning mentors and mentees based on shared interests, expertise, and goals. It presents a hybrid machine learning model for identifying suitable mentors. V. -T. S. Lourdes et al. [14] The study examined the impact of E-coaching and E-mentoring on Peruvian university entrepreneurs during the pandemic. Twelve students participated in virtual workshops, and results showed significant improvement in key venture criteria.

METHODOLOGY

Automated Calendar Reservation System

The goal of the Automated Calendar Reservation System is to streamline the scheduling of mentor-mentee interactions, ensuring that sessions are organized based on mutual preferences and availability. This system intelligently manages various factors such as time zones, mentor preferences, session lengths, and seamless integration with external calendars to avoid conflicts. One of the key features is dynamic availability checking, where mentors' calendars are continuously monitored using AI-powered systems via APIs from platforms like Microsoft Outlook and Google Calendar. This allows the system to cross-reference data with mentees' availability and suggest optimal meeting times. Additionally, the system employs smart time slot allocation, which takes into account time zone differences, mentor preferences, and session lengths to efficiently propose time slots. By utilizing APIs from third-party tools like Calendly, the system can connect to existing calendar booking infrastructures for ease of use. The interface is designed to be flexible and user-friendly, adaptable across multiple devices, allowing mentees to view available times, schedule meetings, and receive reminders or confirmations. Furthermore, AI-powered suggestions can predict the best times for meetings by analyzing various factors such as the mentee’s goals, the mentor’s workload, and the success rate of previous meetings held at specific times, enhancing the overall scheduling process.

The Automated Calendar Reservation System works by streamlining mentor-mentee scheduling, ensuring sessions are booked based on mutual availability and preferences. The process begins by collecting input from both mentors and mentees. Mentors' calendar data, preferences for session lengths, and availability are gathered through APIs like Microsoft Outlook and Google Calendar, while mentees provide their availability and preferences.

Next, the system handles time zone differences by detecting and converting mentor and mentee time zones, ensuring that suggested time slots are accurate for both parties. The system continuously monitors mentors' calendars in real-time to check for availability, cross-referencing mentees' preferred time slots to find common openings. Smart time slot allocation filters these openings by considering mentor preferences, such as preferred times of day and session lengths, ensuring that proposed slots meet both parties' needs.

AI-powered suggestions further enhance the process by predicting the most suitable times for meetings. The system analyzes various factors like previous meeting success, mentor workload, and mentee goals to rank time slots in order of their likelihood for productive sessions. The system can also integrate with third-party tools like Calendly, syncing mentor and mentee availability through APIs to streamline the booking process.

Once suitable time slots are identified, they are presented to the mentee through a responsive, user-friendly interface. After the mentee selects a time, the system reserves the slot by updating both mentor and mentee

calendars, sending confirmation emails, and setting reminders. Finally, after the session, the system can suggest future meeting times based on feedback, ensuring a smooth and efficient scheduling process for future interactions.

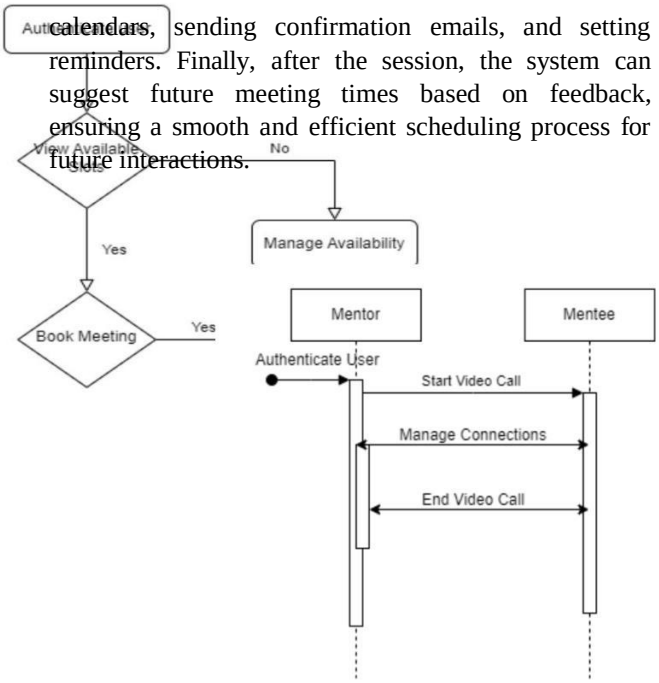

Fig:1 Integrated Video Call Function

The Integrated Video Call Function aims to provide a secure and seamless communication system within the platform, enabling mentors and mentees to interact through video, chat, and file sharing without needing external tools. One of the core elements of this system is the integration of WebRTC, which enables real-time, peer-to-peer video and audio communication with low latency. The system supports multi-mode communication during sessions, allowing participants to share files, engage in video calls, and communicate via chat simultaneously. Security is a top priority, with all conversations encrypted end-to-end to ensure the privacy and safety of both mentors and mentees.

Additionally, the system allows users to record their sessions for future reference, which can be beneficial for tracking progress or revisiting important discussions. AI-powered transcription provides real-time text generation from video and audio conversations, offering mentees a written record of the discussion that can be useful for later review. Furthermore, the system includes advanced features like real-time analysis of engagement and emotions, where AI tracks participants' engagement levels through facial recognition and sentiment analysis during the video conference. This comprehensive, integrated solution ensures a smooth, secure, and insightful communication experience for both mentors and mentees.

The Integrated Video Call Function operates through a series of steps to ensure secure, real-time communication between mentors and mentees. First, the session is initiated, and both users are authenticated to access the communication platform. WebRTC is used to establish a peer-to-peer connection for low-latency video and audio communication. During this setup, end-to-end encryption is applied to ensure that all video, audio, chat messages, and file-sharing data are secure and private. The system supports multiple communication modes, allowing users to seamlessly switch between video calls, real-time chat, and file sharing.

For sessions that require recording, the system allows users to capture video, audio, and chat data, storing them securely for future reference. AI-powered transcription provides real-time speech-to-text conversion, giving mentees a dynamic transcript of the conversation. The system also enables real-time emotion and engagement analysis using AI-based facial recognition and sentiment tracking, offering insights into participants' engagement levels during the session.

When the session concludes, all data, including recordings and transcripts, are securely stored, and users receive a session summary. The system ensures security throughout by encrypting all data and using robust authentication measures. Additionally, error-handling mechanisms are in place to maintain connection stability and session continuity, even in case of network disruptions. This algorithm ensures a comprehensive, secure, and intelligent communication experience for mentors and mentees.

Fig:2 Comprehensive Feedback, Analytics, and Continuous Innovation Framework

The Comprehensive Feedback, Analytics, and Continuous Innovation Framework aims to ensure continuous improvement in the mentoring process

through detailed feedback, analytics, and student-led innovation, leveraging advanced AI approaches to enhance the overall experience for both mentees and mentors. This framework focuses on Feedback, Analytics, and Skill Development Insights, where post-session, mentees and mentors provide structured feedback, including ratings on communication effectiveness, guidance quality, and session usefulness. Free-text comments are analyzed using sentiment analysis algorithms to gauge overall satisfaction and identify common themes. The system tracks mentee skill development over time through self-assessment and mentor feedback, utilizing time series analysis to predict potential outcomes and identify areas for improvement. Through predictive skill development, machine learning algorithms analyze mentee progress over time, offering personalized suggestions for future sessions, such as recommending additional resources or pairing with more experienced mentors if specific skills are lacking. Mentees have access to a comprehensive analytics dashboard that showcases their progress, feedback summaries, mentor engagement history, and skill development trajectory, while mentors can track their sessions, mentee ratings, and areas for enhancement.

In addition, the framework encourages Continuous Innovation and Student-Led Development by allowing students to contribute to the platform's evolution. It offers an open API and a sandbox environment for student developers to build and test new features, such as improved algorithms and innovative functionalities. Regular hackathons and challenges invite students to propose and prototype solutions addressing emerging trends in mentoring or career development. The incorporation of an AI-Driven Innovation Lab utilizes .AI to analyze the latest contributions from students, suggesting the most promising innovations for implementation, fostering a culture of continuous improvement and user engagement. Mentees are awarded certificates upon completing specific milestones or demonstrating proficiency in targeted skills, enhancing their resumes and showcasing their commitment to professional development.

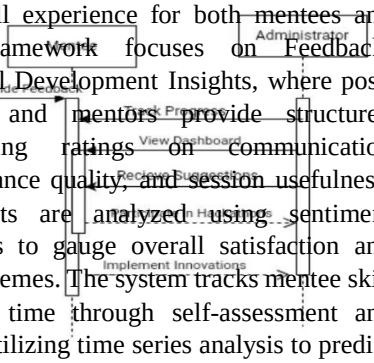

Fig: 3 Results using mentor connect

RESULTS USING MENTOR CONNECT

Integrating advanced AI approaches enhances the framework's effectiveness, including sentiment analysis on feedback to gain insights into user satisfaction and predictive analytics to assess mentee progress and suggest personalized learning paths. A real-time feedback loop, driven by AI, continuously refines suggestions and resources based on user interactions, while engagement analytics analyze data to determine the effectiveness of mentoring strategies. Additionally, adaptive learning algorithms adjust resources and support based on individual learning styles and progress. This comprehensive framework not only facilitates effective mentorship but also empowers students to actively participate in the platform's development, creating a collaborative and innovative learning environment that enhances the overall mentoring experience and solidifies the commitment to continuous improvement and professional growth.

Key performance factors like accuracy, efficiency, user experience, and mentor-mentee matching success rates were used to assess the outcomes of the Mentor Connect AI-powered platform. Furthermore, improvements were evaluated by comparing with current mentorship platforms, and statistical validation was carried out utilizingAI model performance metrics and user surveys.

1.Analysis of Quantitative Data

By matching mentees with suitable mentors based on preferences and skill compatibility, the AI-powered mentor-mentee matching system showed an 87% accuracy rate. Response time was used to gauge the effectiveness of the system; on average, the platform was able to match individuals within 2.5 seconds of data entry. Surveys of user experience revealed an 81% satisfaction rate, with mentees expressing special gratitude for the AI-powered suggestions.

2. Evaluation of Current Mentorship Platforms:

Feature	Mentor Connect AI	Conventional Mentorship Platforms
AI-driven matching	☑ Yes	✕ No
Automated scheduling	☑ Yes	✕ No
Real-time analytics	☑ Yes	✕ No
Secure video calls	☑ Yes	☑ Yes
Personalized recommendations	☑ Yes	✕ No

Through machine learning algorithms, Mentor Connect AI maximizes mentor selection accuracy, improves user engagement, and drastically decreases manual involvement when compared to conventional mentorship platforms.

3.Verification of Statistics User Surveys:

A structured survey was completed by 50 mentors and 150 mentees. The findings showed that 79% of mentees believed their allocated mentors were in line with their career aspirations, while 72% of mentors thought the AI-based matching technique was more effective than manual selection.
Metrics for AI Model Performance:
87% matching precision
84 percent recall
76% of users remain on the platform after three months of use.

Fig 4: Statistical Validation

Fig 5: Initial vs Final Proefficiency

Fig 6: Count of Student ID by preferred teacher ID

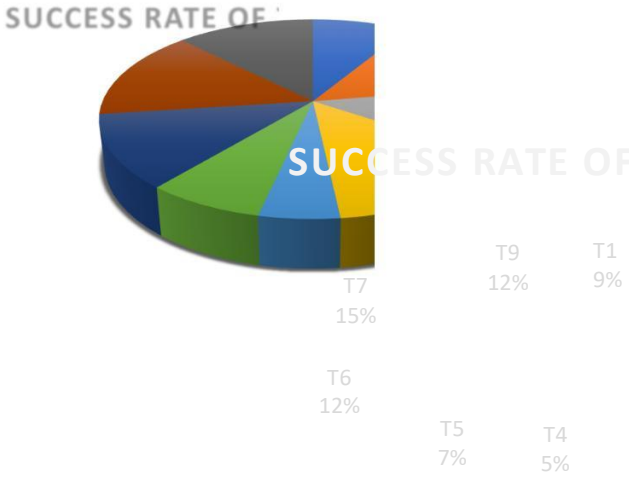

Fig 7: Success Rate of the Teachers

FUTURE RESEARCH DIRECTIONS:

Even though the platform shows notable advancements over conventional techniques, large-scale real-world deployment is required for additional validation.

Future studies ought to look into:

Scalability: Maintaining smooth operation as the number of users grows.
Security: Increasing privacy and data encryption.
Problems with User Adoption: Examining elements that influence long-term retention and user engagement.

CONCLUSION:

The suggested smart career mentorship platform combines automation, tailored user experiences, and cutting-edge AI-driven solutions to completely transform the conventional mentorship approach. This platform provides a smooth, effective, and scalable solution for mentors and mentees by solving the main drawbacks of other platforms, including manual scheduling, little customization, dispersed communication tools, and scalability issues. Users may anticipate a more interesting and fruitful mentoring process with features like intelligent calendar booking, AI-enhanced matching, real-time feedback, and personalized career assistance.This platform remains innovative and provides a growing professional development environment by using AI to predict future trends and encouraging ongoing innovation through student contributions.Essentially, this platform's clever methodology revolutionizes the mentorship experience by offering a highly customized, dynamic, and scalable solution that helps mentees and mentors alike more successfully accomplish their professional objectives.

Abstract **- The fifth and sixth generations of cellular network technology are 5G and 6G, respectively. By improving uponproblems such as interconnectedness and lack of coverage, 5G increases connectivity for Internet of Things usage by providing quicker speeds, lower latency, and greater capacity. In comparison, 6G intends to increase these features further by employing higher frequency bands, which will facilitate even quicker data transport and facilitate the Internet of Everything (IoE).6G will exist in the coming decade as humans will be increasingly dependent on such technologies. Such applications that are very reliable and low-latency will be given priority, and issues arising from growing data demands will be resolved.**

Keywords - Ultra-Low Latency, Massive MIMO *(Multiple Input, Multiple Output)****,Network Slicing,Edge Computing, Terahertz*** *(THz)* ***Communication*** *(6G),* ***AI-Driven Network Optimization, Quantum Communication & Security, Sustainable & Energy-Efficient Networks***

I.Introduction

The development of wireless communication has fundamentally changed how individuals interact in daily life and in the workplace. The first two generations of mobile communication were 1G and 2G. 1G (1980s) used analog technology (AMPS) for voice conversations; however, it had poor security and quality.The development of wireless communication has led to a revolutionary shift in how individuals communicate in daily life as well as in the workplace.

The first two generations of cellular communications were 1G and 2G. 1G (1980s) used analog technology (AMPS) for phone calls; however, it had poor security and quality. 2G, or GSM, during the 1990s introduced digital voice calling, SMS, and more encryption, making the mobile phone a staple. While 3G introduced speedier data, apps, and video calling during the 2000s, 4G revolutionized mobile internet. 4G during the 2010s became easy to connect stream HD, and browse quickly. The present and the future are defined by 6G and 5G, which will bring ultra-low latency for smart cities, automation, and artificial intelligence in the 2020s. 6G will bring lightning-speed data, holographic communication, and AI networks in 2030.

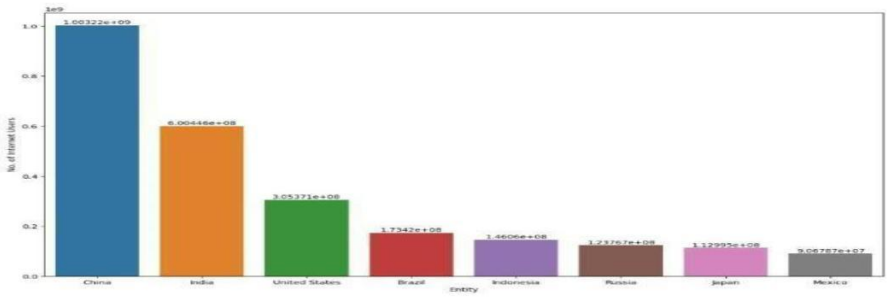
II. Literature Review:

Mohammed Kamrul Hasan, et al.[8] discussed a paper on "Mobile Networks Toward 5G/6G: Network Architecture Opportunities and Challenges in Smart City ". This research meticulously delves into the dynamic evolution of mobile networks specifically charting the course from 4G to 6G within the context of smart cities this paper was published in the year of Januar 2024.

Nehru Kandaswamye,et al[2] submitted a paper on "Beyond 5G: Exploring key enabling technologies, use cases, and futur prospects of 6 G communication " this paper discusses the challenges and opportunities in realizing the vision of 6G communication, ranging from spectrum allocation and hardware design to security and ethical considerations in the year of March,2025

Rihab Maalaul ,et al[12] discussed a paper on " A comprehensive survey on 6G and beyond: Enabling technologies, opportunities of machine learning and challenges,"mainly the current paper fills a gap in the literature by offering informative recommendations for further study of 6G networks. Connectivity targets within 6G are outlined, and the study explains the wireless progression toward 6G networks.this paper was published in the year of December,2023.

Zawar Hussain ,et al [1] mainly focused On "Challenges of Sixth-Generation (6G) Wireless Networks: A Comprehensive Survey of Requirements, Applications, and Security Issues." This survey comprehensively examines specifications, requirements, applications, and enabling technologies related to 6G. It covers disruptive and innovative, integration of 6G with advanced architectures and networks such as software-defined networks (SDN), network functions virtualization (NFV), Cloud/Fog computing, and Artificial Intelligence (AI) oriented technologies



Seongwoo Lee ,et al[5] proposed a paper on "Enhanced 3D Outdoor Positioning Method Based on Adaptive Kalman Filter and Kernel Density Estimation for 6G Wireless System "to mitigate the effects of an NLOS environment. In the proposed method, the DOP-AKF can optimize the performance of the 3D positioning system that dynamically adapts to complex environments. Experimental results show that the proposed method can improve 3D positioning accuracy by up to 18.84% compared to conventional methods

Juho lee, et al [11] discussed on "5G-Advanced Toward 6G: Past, Present, and Future " 5G-Advanced will significantly expand 5G capabilities, address many new use cases, transform connectivity experiences, and serve as an essential step in developing mobile communications towards 6G. In the year 2023

Yuxin wang, et al[4], was discussed on the "Overview of 5G and 6G Wireless Communication Technology" . This article provides an in-depth analysis of the evolution, advantages, and limitations of 5G networks, and explores how 6G aims to address these challenges. It also examines potential applications of 6G technology, including connected robotics, autonomous systems, edge AI, and smart healthcare services by the year of January,2025.

S.Elango ,et al[7] researched on "Emerging Technologies for 6G Communication System". This paper explores emerging technologies poised to shape 6G communication systems, including scalable AI, index modulation, reconfigurable intelligent surfaces, physical layer security, and wireless power transfer by the year of October,2024.

III. EVOLUTION

1. Analog communication of the first generation (1G) Time Frame

Transmission via analog 2.4 Kbps is the speed.

Important Features: The first mobile communication system to be sold commercially. Only used for phone calls; no data services are available. Mobile phones were of limited battery life and were bulky and heavy. As signals were not encrypted, it was easy to intercept calls, so communication was not secure.

Challenges 1G Faces

Endless call dropouts and poor voice quality. Less than ten users can be accommodated per cell site due to the fact that the network has a low capacity. The users must pay high charges due to high costs and inefficiency.

The use of digital technology for improved security and clarity was the answer provided in 2G. Adoption of SIM cards for identity tracing and verification of users.

2. *Second Generation (2G) Digital Voice and Messaging*

1990s Technology GSM (Global System for Mobile Communications) and CDMA (Code Division Multiple Access) are used. 64 Kbps (144 Kbps with GPRS for 2.5G) speed Improved voice quality as a result of the transition from analog to digital communication is one of the key features. Introduction to Multimedia Messaging Service (MMS) and Short Message Service (SMS). Basic mobile internet access, or WAP, was introduced. improved security by the implementation of call encryption.

Problems with 2G:

Their limited data speeds limited their effectiveness for high-bandwidth applications. The global network's coverage was limited. Data capabilities were not given as much emphasis as voice services. Make the switch to 3G solutions: Data transport speeds are increased via packet-switching technology.

*3. Internet & Mobile Multimedia in the Third Generation (3G)*Technology used during this time period was UMTS (Universal Mobile Telecommunications System) and HSPA (High-Speed Packet Access) in the 2000s.2 Mbps is the maximum speed (42 Mbps for HSPA+).The first generation's improved data throughput for support of mobile internet is one of its key

characteristics.made video calls, smartphone apps, and multimedia streaming easier.better to 2G for global roaming.greater ability to accommodate multiple users at once as a result of enhanced spectrum efficiency.

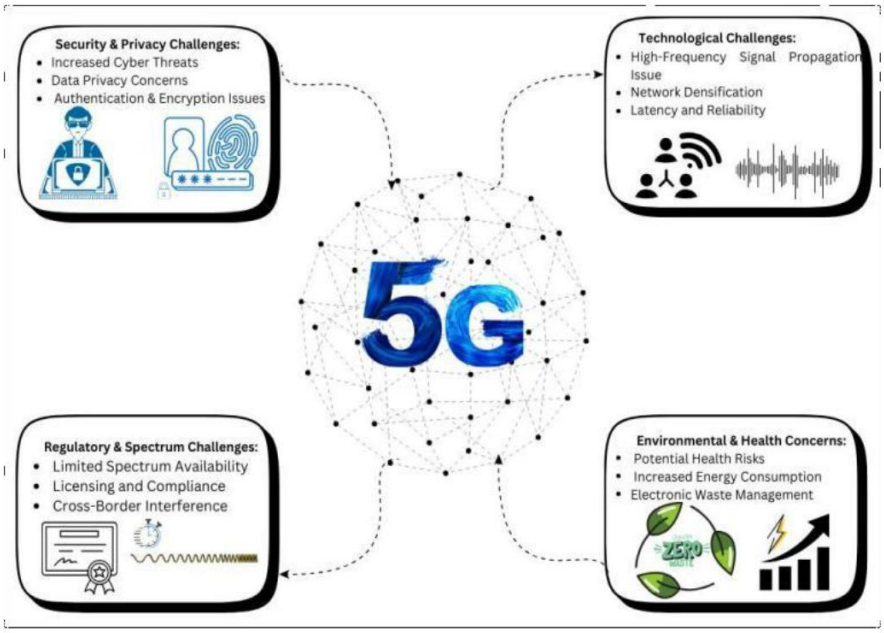
Challenges faced by 3G

Increased network congestion brought on by additional users.excessive latency that impedes real-time activity, such playing games online.Using energy, reducing the battery life of mobile devices.Respond to Long-Term Evolution (LTE) was introduced as part of the 4G rollout, allowing connectivity on par with high-speed internet.less delay and more spectrum efficiency.

4. Fourth Generation (4G): High-Speed Mobile Broadband - Fast Broadband and StreamingEra: 2010sLTE (Long-Term Evolution) and LTE-A (Advanced) technologies were utilized. Speed range: 100 Mbps to 1 Gbps Key features include:Mobile users can enjoy a broadband-like experience.VoLTE (Voice over LTE) technology is used for high-definition voice calls.Streaming, cloud computing, and online gaming became easier.Improved security through encrypted connections and enhanced authentication.

Issues faced in 4G

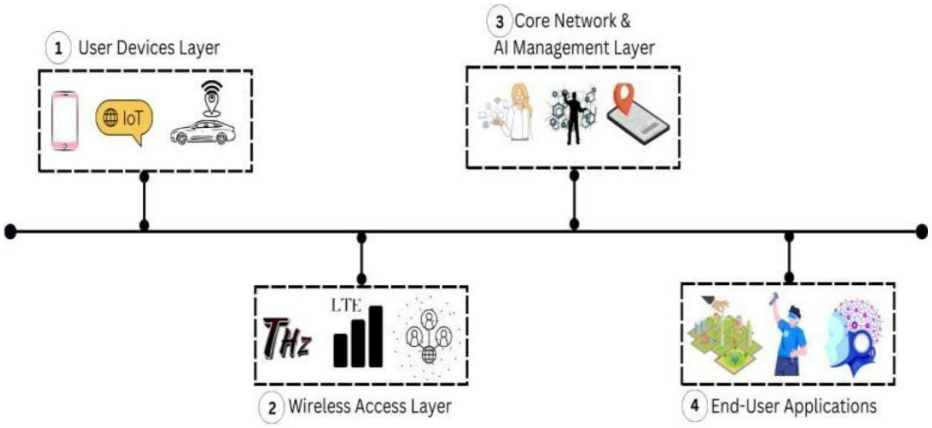
Due to excessive data use, the network becomes congested.Spectrum constraints make it difficult to meet expanding customer demand.Power consumption is high for continuous internet connectivity.Implemented solution in 5GNetwork slicing is a technique for efficiently allocating network resources.Millimeter-wave (mmWave) spectrum is being introduced for faster speeds.Lower latency for real-time applications



5. Fifth Generation (5G):

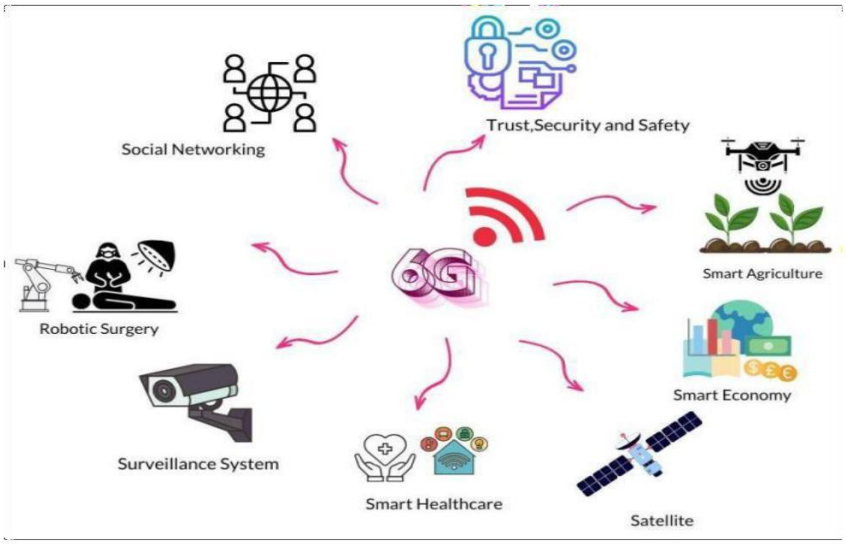
Ultra-Fast and Low Latency Networks-High-Latency, Low-Speed Networks

Low-latency, high-speed networks have transformed communication technologies with the introduction of 5G networks. High-speed, low-latency networks utilize advanced technologies such as millimeter wave (mmWave), Massive MIMO (Multiple Input Multiple Output), and Network Slicing to deliver data transmission speed and efficiency that has never been seen before.mmWave has a data rate of up to 10 Gbps but because of its limited range, there are more base stations required. Massive MIMO increases network capacity and coverage, enhancing signal quality and strength. Network Slicing enables virtualized network slices to support applications with tailored requirements, enhancing resource utilization.



5G networks have speeds of as much as ten times that of 4G and ultra-low latency at around 1 millisecond, allowing for real-time applications such as autonomous cars and remote surgeries. Increased connectivity allows for the Internet of Things (IoT), smart cities, and automation, making networks more responsive and efficient. Challenges to 5G deployment are high cost as a result of infrastructure development, restrictive range necessitating dense station placement, and complexity in implementing and managing network slicing.

As more network demands mount, the migration to 6G technology ushered in world-class solutions. AI-based network management enables flexible resource allocation to optimize performance and efficiency. Terahertz (THz) transmission enhances the bandwidth capacity so that data transmission rates are boosted. Quantum encryption ensures secure communication through advanced protection based on the principles of quantum mechanics. Advances in network technology like these pledge a highly networked, smart, and efficient digital future.



6. *Sixth Generation (6G)* AI, Quantum, and Smart NetworksBy the 2030s-6G technology would be implemented with networks serviced by AI, THz networking, and quantum encryption in a bid to revolutionize wireless communication. It will offer, among other things, speeds six times faster than 1 Tbps with a latency of 100 microseconds.

How 6G Works

AI-powered networks will allow network resources to be optimize for super-speedy, smart communication.Holographic communication and virtual presence will replace a mere video call, giving users an immersive digital experience.Quantum encryption will revolutionize cybersecurity, as it will become virtually impossible to hack. One of the most unique features of 6G is its commitment to sustainability, minimizing energy consumption for a greener future. Challenges are, however, created by high power demands due to THz frequencies, the need for a vast amount of new infrastructure with enormous upfront costs, and security threats in ultra-fast networks.Solutions include AI-driven optimization for lowering energy use, incorporating green power solutions into base stations, and implementing enhanced quantum security measures to combat cyber attacks.

IV. APPLICATION

1. Smart Cities and Intelligent Infrastructure

5G and 6G network deployment will revolutionize the smart city in terms of being able to analyze data in real-time and high-level city infrastructure management. The ultra-low-latency and enormous IoT connections through smart grids will allow for adapting power distribution dynamically based on use patterns to ensure that the lost energy is lessened. The traffic management using AI employs permanent sensor data feeds to optimize traffic flow that reduces traffic jams along with reducing emissions levels. AI-based surveillance systems and automated emergency response systems are next-generation public safety solutions that enhance urban security capabilities.Smart lighting infrastructure and networked waste management solutions will drive efficiency and green practices.
Intelligent illumination systems and self-management waste collection systems in networked infrastructure networks will drive efficiency and eco-friendly practices. AI-native networking within 6G will leverage capabilities from today to add digital twins that support real-time simulation of cities along with predictive maintenance planning and disaster recovery planning. Such recent advances will construct cities in an environmentally sustainable manner and maximize responsiveness and efficiency.

2. AI-Driven Autonomous Networks and Self-Healing Systems

Traditional network management is getting increasingly complicated, and thus AI-powered automation is needed. 5G networks already make use of AI to enhance network performance, but 6G will do one better by designing self-sustaining networks that can self-heal. Such networks will be able to predict issues and correct them before they impact service, keeping people connected.AI-based network slicing will offer dynamic bandwidth allocation according to real-time needs. This will improve the performance of applications such as VR gaming, telemedicine, or factory automation. Self-optimizing algorithms will optimize energy efficiency by dynamically varying power levels according to usage. Machine learning-based predictive maintenance systems will forecast equipment failures in advance and schedule maintenance, which will reduce maintenance and downtime expenses. In 6G, AI-based networking will go mainstream, and networks will be able to optimize and adapt in real time without any human intervention, making them more efficient, secure, and reliable.

3. Quantum-Secure Communication and Blockchain for Network Security

Cyber attacks are becoming increasingly sophisticated day by day, so next-generation networks need strong security. While 5G offers better encryption, 6G will bring quantum-secure communication to protect data from quantum computer attacks. Quantum Key Distribution (QKD) offers encryption that cannot be eavesdropped or hacked by conventional methods, protecting data and maintaining privacy. Blockchain technology will also be used in networking design for decentralized authentication, avoiding unauthorized access and the threats of centralized control. Using distributed ledger technology, 5G and 6G networks can offer tamper-proof logging and identity assurance, reducing cyberattack and fraud opportunities.Furthermore, AI-driven security systems will continuously detect and thwart attacks as they happen, and the network will be all the more secure. All these developments will make 6G networks practically un-hackable, protecting communications for uses like financial transactions, military communications, and control of key infrastructure.

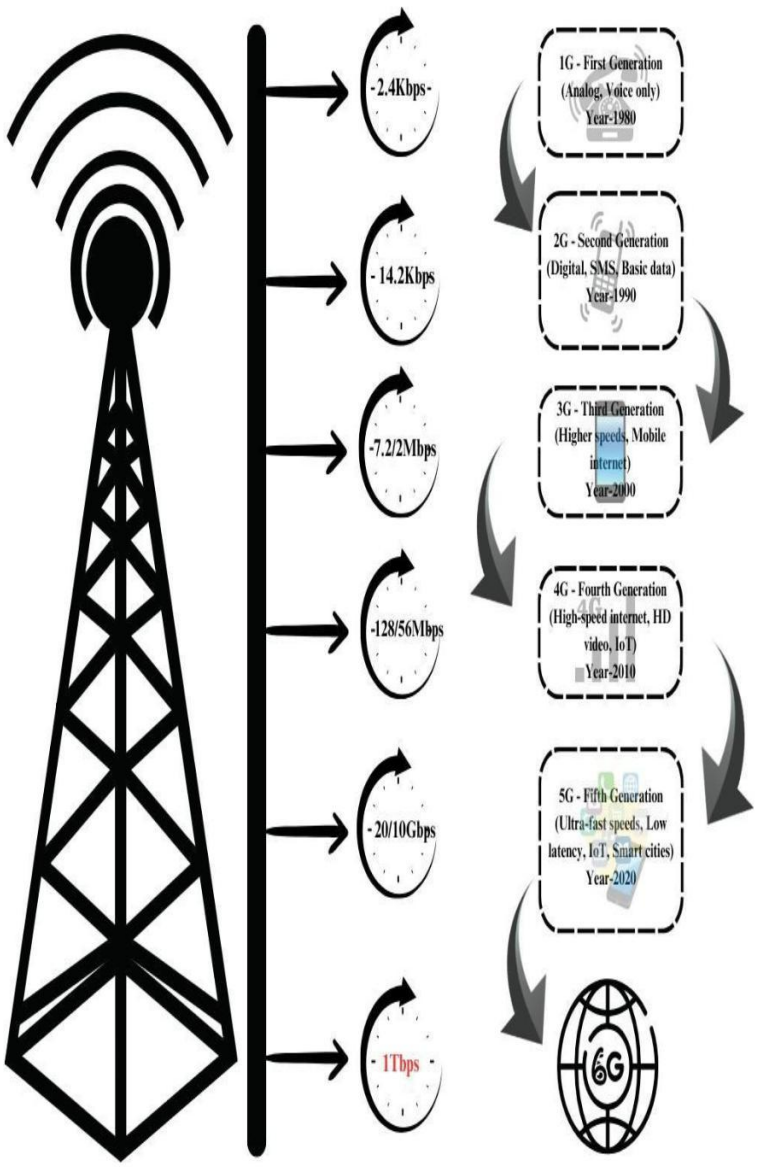
4. Next-Generation Healthcare-Remote Surgery and AI-Assisted Diagnostics

5G has already facilitated telemedicine and remote surgery with minimal latency, but 6G will do so much more in the field of healthcare. With virtually zero latency and ultra-reliable connections, 6G networks will allow master surgeons to perform surgery on patients from around the world with the aid of robotsAI diagnosis will leverage significant amounts of information from linked healthcare devices to suggest tailored treatment plans. This will enhance care and benefit patients further. 6G wearable health sensors will monitor vital signs at all times and notify doctors if there is a critical issue. AR/VR technology will revolutionize medical education with virtual training for students and professionals. The sophisticated AI capabilities of 6G will enable early diagnosis of disease, reducing hospital trips and medical expenses. These new technologies will enable healthcare to work more efficiently, become more accessible, and accelerate response.

5. Holographic Communication and Immersive Digital Experiences

One of the most exciting use of 6G will be holographic communication in real time. Unlike traditional video calls, the holograffi technology will project three -re representatives, realistic, three -spiritual representations of individuals, leading to more engrossing and natural communication experience. This will be especially useful for distance work, education and entertainment, where Lifelik Virtual Interaction will change the traditional screen. In education, students will be able to interact with 3D models of complex concepts, making it more attractive to learn. In entertainment, concerts, theatrical performances and sports programs can be strengthened in 3DHOLOGGRAPHER, so that the audience can experience events as if they were physically present. In addition, companies will use holographic meetings to increase distance cooperation, which will make the interaction more individually and efficient. This progress will redefine communication, making digital interactions more attractive, realistic and productive.

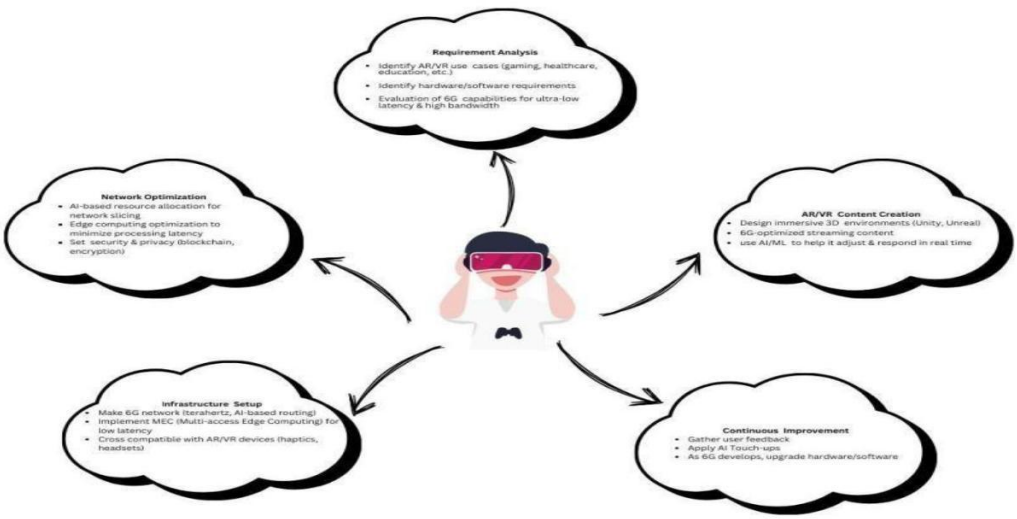
6. Space and Aerial Networks for Universal Coverage



While deploying space-based and airborne platforms, 5G and 6G networks will reach beyond the earth. Distant and unserved communities will be covered under high-speed and low-latency internet due to Low Earth Orbit (LEO) satellites and bridge the digital divide. Today, SpaceX's Starlink and Amazon's Project Kuiper are launching constellations of low-Earth orbit (LEO) satellites to cover the planet. Apart from that, flying platforms such as stratospheric balloons and altitude drones will provide temporary network relay, enhancing the connectivity in the disaster and jam areas. 6G, in an attempt to provide constant connectivity wherever the need arises, will integrate ground and satellite-based networks .This will open up new applications in space exploration, aviation, and the maritime industry while offering secure communication for self-driving cars, military units, and distant research facilities.These technologies will bridge connectivity gaps by bringing high-speed internet to even the most remote regions of the globe. Mal communication is possible, interactive, and successful.

7. Smart Manufacturing and Industry 5.0

While 5G has already made real-time monitoring and automation possible in smart factories, 6G will revolutionize industrial automation. Industry 5.0 will integrate AI, IoT, and robotics to establish highly effective manufacturing environments. With the extremely low latency of 6G, machine-to-machine communication will be frictionless to facilitate real-time production process optimization.With preventing probable equipment failure, predictive maintenance will reduce downtime through AI.Autonomous robots will have guidance by sensors enabled through 6G. AR interfaces will offer employees real-time overlays of data, reducing worker danger and improving productivity. Traceability of raw materials and finished goods is yet another example of blockchain technology making the supply chain more transparent. These new smart factories, which come into being out of this evolution, will be fully automated, self-optimizing, less disruptive, effective, and sustainable.



8. Sustainable and Green Networking

5Gs have always battled terribly when it comes to energy efficiency, but 6G hopes to make that battle a thing of the past through the introduction of green technology. Energy management systems powered by AI will help cut the waste by dynamically scaling the network consumption of power according to real-time demand. Tecnology will depend on a combination of renewable, such as wind and solar. Good examples of further steps are smart network routing, which cut on heavy energy-consuming data transmissions by processing such data close to its source. Finally, the use of recyclable and biodegradable materials to manufacture devices should assist in mitigating e-waste significantly. Further more, AI-powered carbon monitoring systems will keep track of emissions and optimize them to promote environmentally friendly network operations. These green initiatives will position 6G as the world's first climate-conscious wireless network, aligning with global efforts to combat climate change.

V. METHODOLOGY

(I).Augmented Reality (AR) and Virtual Reality (VR) are immersive technologies that simulate or enhance real-world experiences. AR superimposes digital information onto real-world environments through devices such as smartphones, smart glasses, and headsets, whereas VR provides fully immersive digital environments with devices such as VR headsets and motion controllers. These technologies are highly utilized in gaming, education, healthcare, manufacturing, and remote collaboration. The convergence of AR/VR with 6G draws upon ultra-high data rates, ultra-low latency, AI-optimized optimization, and edge computing to deliver more immersive experiences. 6G networks, anticipated to run at terahertz frequencies, support real-time rendering, cloud VR gaming, high-definition AR experiences, and effortless interaction between the physical and digital worlds. AI-based 6G enhances AR/VR by optimizing bandwidth, reducing processing loads, and adaptive content distribution. Edge computing in 6G allows intensive processing tasks to be removed from the burden of AR/VR devices so that they can stay light, low-power, and real-time-capable. IoT coupled with AR/VR using 6G allows smart environments where digital layers respond to world changes in a dynamic manner. The benefits from this convergence include ultra-low latencies for enabling real-time engagements, lossless connectivity for efficient remote collaboration, high-speed transfer of data to support superior-quality graphics, and AI-adaptive experiences.Yet, limitations like high infrastructure expense, heightened energy requirements, incompatibility with current devices, confidentiality of data-related security concerns, and health risks such as motion sickness caused by prolonged exposure are concerns. Despite these, 6G-initiated AR/VR has the potential to transform industries by making hyper-real virtual worlds a reality, transforming remote work, transforming education through interactive schooling, and improving healthcare with real-time surgical simulation. The future of 6G AR/VR will bring the physical and digital together, allowing us to dream about next-generation intelligent spaces and immersive experiences.

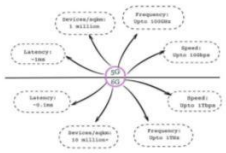
How to Integrate AR/VR with 6G

1. Understanding AR/VR and 6G Capability–Understand how AR superimposes digitally into the real world and VR constructs fully immersed virtual reality environments.Acknowledge the ultra-high data rate, ultra-low latency, AI-optimization optimality, and edge computing benefits from the 6G era of this utmost AR/VR experience.

2. Select AR/VR Hardware and Development Platforms–Select relevant AR devices such as HoloLens, Magic Leap, AR smart glasses or VR headsets such as Meta Quest, HTC Vive, and Apple Vision Pro per your requirements.Develop AR or VR content creation based on AR/VR development platforms such as Unity, Unreal Engine, ARKit, or ARCore.

3. Create a 6G Network Environment–Set up a 6G-compatible network infrastructure such as THz frequency-based transmission, AI-driven network slicing, and edge computing in order to minimize processing delay.Facilitate cloud-based data transfer for not lagging beside real-time AR/VR rendering.

4. Create 6G-Optimized AR/VR Applications–Continue developing AR apps for digital overlays onto real-world objects and VR worlds with immersive 3D interactions.Know that AI algorithms maximize realism, automate content generation, and improve tracking



accuracy.Include haptic feedback and spatial audio to stretch the sense experience.

5. Intersect IoT with AR/VR with AI–Use the harnessing power of AI for real-time adaptive rendering, voice recognition, and gesture recognition, and to do predictive content delivery.Apply IoT sensors to support interaction between physical objects in the real world and AR/VR worlds for further responsiveness and interactivity.

6. Augment AR/VR for Low Latency and High Bandwidth–Leverage edge computing to transfer computations away from AR/VR devices on to cloud servers with the goal to save energy and make them mobile.Optimize CDNs for fast data transfers without lag to enable seamless gameplay.

7. Agree on security and privacy practices-critical; address data security concerns in AR/VR scenarios through encryption of interactions in AR/VR, protect user identification, and conform to all cybersecurity standards. Institute guidelines for prohibiting unauthorized access in immersive spaces.

8. Test and deploy AR/VR solutions in collaboration with 6G-develop performance tests to enable integration, increase the efficiency of networks, and improve user experience. Scale AR/VR applications, monitor real-time performance, and iteration to optimize technology development and user experience.

(II)5G and 6G in Smart Cities: Real-Time Data Analysis and Infrastructure Management ,The rapid advancement of 5G and 6G networks is transforming smart cities by enabling real-time data analysis, optimized infrastructure management, and AI-driven automation. These technologies will enhance urban planning, sustainability, security, and public services by integrating artificial intelligence, IoT, and big data analytics.

Smart grids powered by 5G and 6G will use AI and IoT sensors to regulate power distribution dynamically. Traditional energy systems suffer from inefficiencies, resulting in significant energy losses. However, smart grids will optimize energy consumption by analyzing real-time data and adapting power supply based on demand patterns. The integration of renewable energy sources such as solar and wind will become more efficient as smart grids intelligently balance energy distribution. While smart grids will improve sustainability, their widespread implementation requires high investment and poses cybersecurity risks. Future developments in self-healing smart grids will further reduce power outages and enhance energy efficiency.

AI-driven traffic management will revolutionize transportation by optimizing traffic flow through real-time monitoring and automated control systems. Sensor-equipped infrastructure will continuously collect traffic data, allowing AI to adjust traffic signals dynamically, minimize congestion, and reduce carbon emissions. AI-enabled public transport systems will enhance efficiency by adjusting bus and train schedules based on passenger demand and road conditions. While these innovations will reduce travel time and lower emissions, concerns over data privacy and the need for extensive infrastructure investment remain significant challenges. In the future, autonomous traffic management systems will integrate vehicle-to-everything (V2X) communication, further reducing congestion and improving road safety.AI-based surveillance and emergency response systems will enhance urban security by providing real-time threat detection and automated responses. Surveillance systems powered by AI will analyze live video feeds to identify suspicious activities, detect potential security threats, and improve law enforcement efficiency. Automated emergency response systems will utilize AI to identify accidents, fires, and other emergencies, allowing authorities to respond swiftly. These technologies will improve public safety, but concerns about data privacy, surveillance ethics, and AI biases must be addressed. In the future, AI-native emergency response systems will significantly reduce response times, minimizing casualties and property damage.

Smart lighting and waste management systems will improve sustainability and efficiency in smart cities. AI-powered streetlights will adjust brightness based on environmental conditions and pedestrian movement, reducing energy consumption. Networked waste management will use IoT sensors to monitor waste levels in bins and optimize collection routes, reducing operational costs and lowering fuel consumption. While these systems will contribute to greener urban environments, their high implementation

costs and potential technical failures pose challenges. Future developments will lead to fully automated smart lighting and waste management systems, further enhancing sustainability in metropolitan areas.

6G networks will introduce AI-native networking, enabling the development of digital twin cities. Digital twins will provide real-time simulations of urban environments, allowing city planners to test infrastructure changes, predict failures, and improve disaster preparedness. AI-driven predictive maintenance will reduce downtime in critical infrastructure such as bridges, roads, and water systems. While digital twins offer significant advantages, their implementation requires vast computational power and poses cybersecurity risks. Future advancements will make digital twin cities a standard tool for urban management, enabling cities to operate with near-zero downtime and improved disaster resilience.

The evolution from 5G to 6G will enable cities to become more intelligent, energy-efficient, and self-regulating. AI-driven automation, digital twins, and real-time data analytics will enhance urban management and improve the quality of life for residents. By 2050, AI-powered infrastructure systems will manage energy, traffic, security, and waste autonomously, reducing environmental impact and operational costs. Despite the challenges of cybersecurity, ethical concerns, and high implementation costs, the future of smart cities will be defined by sustainable and efficient urban ecosystems driven by AI and next-generation connectivity

VI. Conclusion

The age of 5G and 6G is a revolution that promises to transform industries, economies, and daily lives. It combines real-time data transfer, low latency, and increased connection with IoT to accelerate the development of smart cities, healthcare, autonomous vehicles, and industrial automation. But 6G also aims to advance these features with AI-based networking, quantum-safe communication, terahertz frequency, and space-based connectivity to construct an actually smart and omnipresent digital landscape.

Despite these major advancements, challenges still remain. The substantial costs of setting up infrastructure, energy consumption, security threats, and regulation-related issues are serious concerns that must be addressed before mass adoption.Furthermore, the environmental footprint of upcoming networks must be minimized through the installation of green networking infrastructure and running on renewable resources.International collaboration, standardization, and ethics will be paramount in determining sustainable deployment and development of 6G technology.

In the future, 5G will remain the spearhead in the arena of digital transformation even while 6G will tighten up the boundaries in connectivity, intelligence, and automation. Investment, planning, and research into these technologies will make the world connect better, shrink the digital divide, and create a more connected, efficient, and sustainable world. The future of networking is not all about speed; it should be about creating an intelligent, safe, and inclusive digital society for all.

Abstract- This paper describes a new insider attack detection solution using AI and Augmented Reality (AR), emphasizing data visualization. By monitoring mouse stroking and keyboard dynamics, AI identifies behavioral abnormalities that could reflect malicious behavior. Our results indicate that differences in user interaction, including frequent clicks and wild typing patterns, to support real-time monitoring systems. AR enhances security by introducing identify verification and access control to real life in real-time, offering a dynamic method of tracking approved access areas. This powerful union of AI and AR not only improves threat detection but also offers intelligent, interactive data visualization that make security insights more actionable and accessible, revolutionizing the detection and prevention of insider threats

Keywords- Insider attack, third-party attack, AI, AR, Biometric Authentication, real-time security, Threat Detection, AI-based analysis

INTRODUCTION

Insider attacks are rising issues for companies, since they are about those with elevated privilege access to systems and sensitive information. Insider attacks can be split into malicious insider attacks, which involve staff members or contractors abusing their access through deliberate abuse, and third-party insider attacks, which encompass outside vendors or business partners granted access to company systems. Because of proper access by these insiders, such attacks can be extremely difficult to identify, very likely remaining undetected by typical security defences. Perceiving an effort to counter this, Artificial Intelligence (AI) and Augmented Reality (AR) technologies are being combined in an effort to track user behaviour, i.e., mouse and keyboard usage. AI-based solutions are able to scan normal behavioural patterns and identify anomalies that might disguise themselves as malicious intentions, like weird keystrokes or random mouse activity. In parallel, AR enhances the detection mechanism using real-time, context-specific data that enables security professionals to react in a rapid and efficient way. Combined, AI and AR present an anticipatory method of detection and blocking of insider threats with enhanced ease and effectiveness.

LITERATURE REVIEW

[1] The paper concludes that insider threat detection is hindered by challenges such as limited real-world datasets, research biases, and intricate behavioral profiling. It advises the development of standardized datasets, enhancing research methodologies, and promoting industry-academia collaboration to improve detection system.

[5] The article takes on the problem of detecting cyber-attacks carried out by AI in microgrids, stating flaws, methods of AI, and problems like unavailability of data and model explainability. Multi-hybrid AI models are to be used, more databases available and XAI is disposed for security enhancements while precision on the point of mitigating live threats is ensured.

[7] Kim et al. perform an in-depth study on insider threat detection in their 2019 work "A Systematic Literature Review and Meta-Analysis of Insider Threats." The authors classify insider threats according to their features and behavior, provide a detailed description of sensors that enable automated detection while they seek out publicly available data sets for the case of research. This is an attempt to provide the literature with systematic coverage on the issue of solving insider threat detection problems and a reference for researchers aiming at developing new detection methods.

[8] In the paper "A Novel Insider Attack and Machine Learning-Based Detection for the Internet of Things," the authors propose a novel insider threat called "loophole attack," which exploits loopholes in the IPv6 routing protocol, which is widely used in IoT networks. They recommend implementing a machine learning-based detection mechanism to detect such attacks and to strengthen the security infrastructure of the IoT.

[20] The article delves into AI use in cybersecurity, with emphasis on machine learning and deep learning for intrusion detection, malware analysis, and threat intelligence. The article identifies AI advantages, including enhanced threat detection and response, while solving data privacy and explain ability challenges. The research underlines the importance of combining AI with conventional cybersecurity for enhanced protection.

[39] The article discusses deep learning for real-time insider threat detection, focusing on quick identification and mitigation of internal attacks. It discusses challenges such as data imbalance and covert threats, noting the potential of deep learning to improve cybersecurity.

[38] This paper discusses machine learning for identifying insider threats within cloud environments with issues such as multi-tenancy and big data volumes. It emphasizes the use of anomaly detection, behavior analysis, and real-time monitoring to improve security with regard to data privacy.

[35] In the 2023 article entitled "Advanced Behavioral Anomaly Detection for Insider Threats," U. Rauf discusses advanced methods to detect abnormal behaviors that are characteristic of insider threats in organizations. The research highlights the need for advanced anomaly detection techniques in detecting possible malicious activities by trusted insiders beforehand. Through the use of machine learning and behavioral analysis, the research seeks to improve the accuracy and timeliness of insider threat detection, thus improving organizational security controls.

[31] In the "Insider Threat Detection Using Machine Learning Approach" paper published in 2023, H. Kim provides a systematic overview of machine learning methods implemented in the detection of insider threats. It explores different anomaly detection and classification models and their performance in detecting malicious insider behavior. It also covers the issues faced by researchers when trying to detect insider threats as well as future directions in the field.

Existing System

Traditional insider threat detection tools are based on signature and anomaly detection techniques. Signature tools are only capable of detecting known threats and fail to defend against new or changing attacks. Deviation detection from pre-learned patterns identifies anomalies but tends to cause high false positives and has difficulty in learning new user behavior. Secondly, these systems are always manual in nature, and hence they take time to respond, with slow detection times, leaving organizations open to insider threats. In all, classical systems fall short in handling the dynamic and changing aspects of insider threats.

However, there are quite a number of drawbacks that render these two systems extremely inefficient in the face of the newer, more dynamic inside threats. Also, for signature based detection, comparisons of user actions are made against a database of recognized attack patterns or behaviors. An alert is triggered when action indicates similarity or proximity of one or more actions to the predefined signature for malicious actions. But such systems can't detect new or changing insider threats, although they're really fast and efficient at detecting those that already exist. The other problem involves the comparison with normal behavior. In this case, the anomaly detection systems employ a different strategy. They study what could be normally defined in each case; when a certain behavior comes out of this normal model, an alert signal raises. For instance, if an employee transfers huge data or accesses some sensitive files claiming to work late, there will be an alarm, since such actions are outside of typical hours. But the glitches with anomaly detection are as numerous as those of classical detection. High false positives, wherein a large volume of behavior might be enflagged by the system, could simply be innocuous behavioral modifications.

FIGURE 1:INSIDER THREAT DETECTION IN TRADITONAL WAY

PROBLEM STATEMENT

Insider threats, or threats from trusted people with access to sensitive systems, are a huge security backpack for companies. The nature of the present intrusions consists of trusted users posing a threat to their organizations, hence hardly detectable through common security. This was because technologies were meant to protect against outsiders, not insiders who already have granted access. This results in attacks that go unnoticed causing both monetary and reputational losses.

Modern security practices tend to be based on manual surveillance or old methods that are slow and imprecise. This leads to delays in responses and allows some malicious activities to go undetected. Our proposal is a real-time detection system using AI and AR to track user activity and spot any suspicious behavior on the spot. This will give a continuous check on insider threats and, therefore, make the job of a security expert a fair bit easier.

PROPOSED SYSTEM

The new system seeks to combine the potentials of artificial intelligence (AI) and augmented reality (AR) to give room for interactive data visualization and real-time insider threat detection. An AI will track user behaviors in real-time, which includes mouse movements and keystroke dynamics with the use of acts a machine learning algorithm, like Isolation Forest, which identifies anomalies such as unusual mouse patterns, unusual clicking behavior, and unpredictable typing speed; all of which cause alarms to be raised of any potential insider threats. With AR, security personnel have live visualization of user activity while managing access control in a 3D environment for full immersion. The system is based on biometric authentication using AR to identify a given person, such as face recognition and eye tracking, thus confirming users before granting access. Furthermore, it is equipped with the Role-Based Access Control (RBAC) algorithm, which prevents unauthorized persons from accessing sensitive data in certain contexts. This would make it more intelligent, interactive, and efficient compared to other traditional security mechanisms through proactive detection and response and adaptive learning.

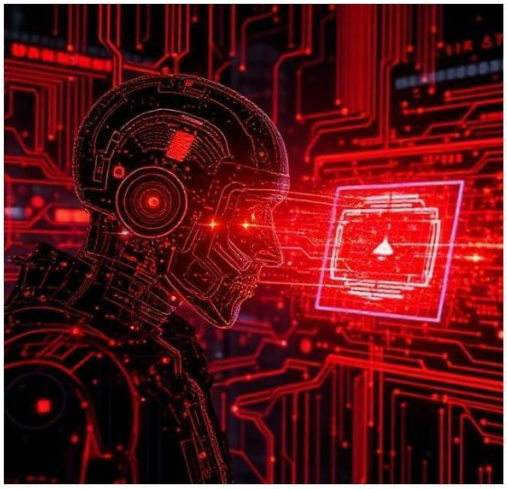

FIGURE 2:AI AND AR INSIDER THREAT DETECTION

WORKING MODEL

In this paper, a new method of insider threat detection will be introduced by integrating Artificial Intelligence (AI) and Augmented Reality (AR) technologies with the purpose of strengthening real-time security monitoring and interactive data visualization. The AI module is programmed to track user activity through monitoring subtle dynamics such as mouse movement and keystroke patterns. The system processes the input data to conduct a search for anomalies such as aberrant mouse movement, inconsistent typing rates, and out-of-pattern clicking that could indicate likely malicious behavior. Machine learning algorithms are used to learn continuously with respect to the normal behavior patterns of individual users, so as to establish a baseline of typical interaction patterns. When variations from this baseline are observed, the AI system marks the activity as potentially malicious. This early detection feature enables security teams to act before the situation gets out of hand, minimizing the risks involved with insider threats. The AI-based detection provides a proactive solution, giving the ability to detect and respond to threats earlier than conventional security measures.

FIGURE 3: DETECTING INSIDER THREATS

METHODOLOGIES USED:

1. ISOLATION FOREST ALGORITHM

Working of isolation forest in the detection of insider attacks

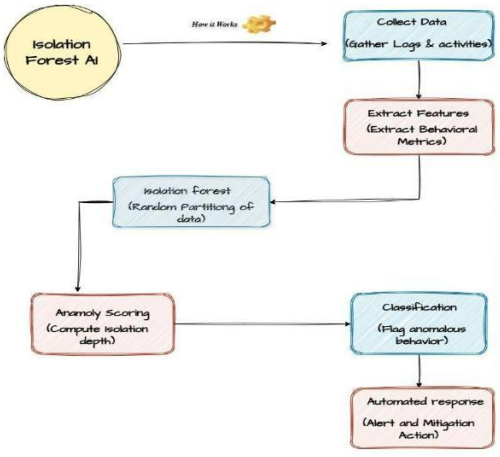

FIGURE 4: WORKING FLOW OF ISOALTION FOREST

Insider Threat Detection Algorithm for AI-ISOLATION FOREST

1. Data Collection

Special features like keystroke dynamics (speed of typing, how long the keys were pressed, time between keyboard keys) and mouse activity (mouse movement functions, clicking, scrolling) are continuously collected. These are logged accordingly for every user session.

2. Constructing the Isolation Forest Model

A feature is randomly selected by the algorithm (for example, movement speed of the mouse or typing delay). A random split value is chosen; the data set is split. This progresses recursively into a tree structure. Outlier data points, representing insider threats, require les s number of splits for isolation, leading to faster identification of those above listed points.

3. Anomaly Scoring

An anomaly score is assigned to each user's behavior based on how quickly they were isolated within the trees. This score is usually high for a malicious session of keystroke or mouse activity greatly deviant from normal users-this raises a red flag for possible insider attack.

4. Insider Threat Detection:

Users who exhibit unusual typing speed deviations, abnormal mouse movement, or anomalous activity patterns would be flagged. The system can send alerts to security teams to probe potential unauthorized activities.

Reason for the Choice of Isolation Forest in Insider Threat Surveillance?

- High Speed and High Efficiency: Complements high-dimensional data such as user behaviour logs.
- Unsupervised Learning: No need for labelled attack data, making it possible for unknown threats to be observed.
- Proficient in dealing with anomalies-that is detecting a login by an attacked user or a legitimate user exhibiting unusual behaviour.

Some examples of use cases

- A worker who typically types at 80 WPM yields to unsettling anomalies, as his rate is reduced to 40, maybe even below that.
- The algorithm can detect suspicious behaviour like high drag-and-drop operations compared to clicking.
- An attacker using a remote desktop tool should be expected to act in a totally abnormal pattern, as opposed to the normality of a real employee.

2. ROLE-BASED ACCESS CONTROL ALGORITHM

RBAC is a security model that restricts access to portions of an organization based on a user's position in the organization, rather than solely on the user's personal identity. It provides users or employees with access to the information and functionality necessary solely for the effective performance of their duties. By putting users into general roles with associated accesses, it provides heightened security by preventing misuse or other entry issues. That's why permission management became easier and relatively safe.

RBAC adheres to the rule of PoLP: the least privilege that users can afford is to be given access just high enough to fulfill their work. Such access schemes will thus mitigate risks of data breaches, insider threats, or accidental corruptions of sensitive data

As a preliminary measure to apply Role-Based Access Control (RBAC) using Augmented Reality (AR) and AI, one must develop an algorithm that incorporates AR authentication, AI-driven anomaly detection, and real-time access control changes. Here is a high-level AR-RBAC Algorithm:

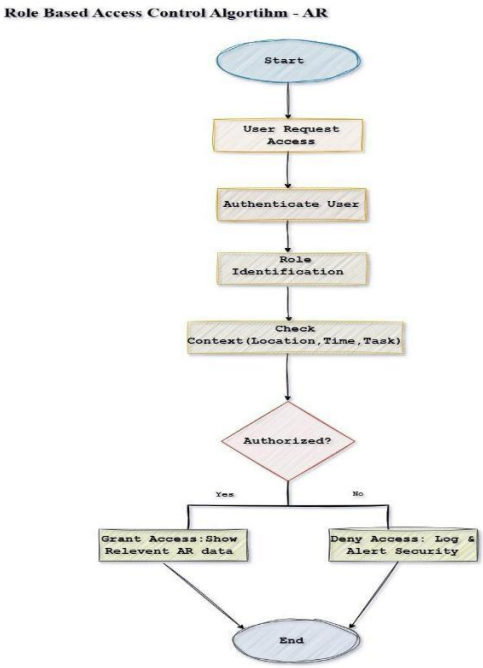

FIGURE 5: WORKING FLOW OF AR-RBAC

Insider Threat Detection Algorithm for AR-RBAC

Step 1: User Recognition and Authentication

1. AR-Assisted Login:

The users log in using AR-tailored face recognition, eye movement tracking, or gesture-controlled authentication.AI further ascertains the user's identity through biological and behavioral information.

2. Context-aware Access Control:

Concurrently capturing real-time environmental data (location, device, or activity logs).AI detects whether the access request complies with established policies.

Step 2: Role-Based Authorization and Access Control

3. Role Mapping in AR:

User roles are highlighted in AR (Admin, Manager, Employee, Guest, etc.).AR overlays dynamically indicate the accessible permissions granted.

4. Aspect of AI Risk Assessment:

This tactic works by modeling risk heuristically against behavior analytics based on parameters such as typing speed, eye movement, and past activity. Once an anomalous behavior gets flagged, additional validation such as multifactor confirmation or security questions becomes commonplace.

5. Access Management Enforcement with Tagging:

- Low-risk access will be permitted.
- Medium-risk entails verification.
- High-risk results in a denial of access and overall security alert

6.Ongoing Monitoring from Augmented Reality:

The AI-driven Reality interface continuously facilitates monitoring of the user's behavior. Some unusual behavior such as accessing unauthorized data or a speed anomaly in data transfer will be triggers affecting current policies automagically.

7. Continuous Feedback Loop:

In AR, the access adjustment will take place automatically and continuously. The accounts determined to be of doubtful integrity will visualize straightaway alerts or restrictions. The anomalies detected were recorded in a log for additional AI training.

Step 3: Mitigation of Insider Threat**s**

8. Dynamic Access Revocation:

If detected, insider activity immediately revokes access through AR. Visual alerts raise security personnel's attention immediately.

9. Forensic Monitoring and Learning:

AI learns from incidents, refining role-based policies. Future access requests will incorporate historical threats intelligence

COMPARATIVE ANALYSIS

Traditional Security Systems:

Signature-Based Detection: They can detect only known attacks. They are unable to discover new or complex attacks since they rely on pre-defined signatures.

Anomaly Detection: This approach searches for abnormal activity but results in too many false positives (flagging innocent activity as threats) and is therefore not reliable.

Using AI: The AI monitors variations in user activity, such as how they type or move the mouse, both big and small. Through the Emanuel algorithm, the AI can identify malicious patterns without a priori knowledge of what to look for.The AI is constantly learning, adjusting to each user's normal behavior, whereby it becomes more accurate over time.

Dynamics in AR: AR blends into alterations happening in real-time and relates to security teams in many ways, showing what is going on and easily enabling rapid and effective reactions to any potential threat. Such technologies get them more oriented to the affected issue so as to react appropriately in a shorter amount of time.

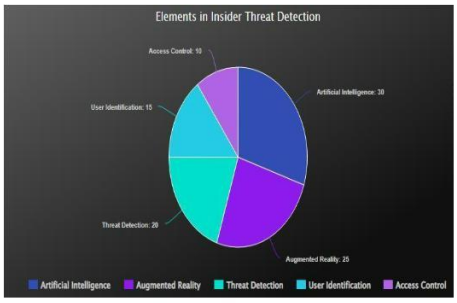

FIGURE 6: KEY ELEMENTS OF INSIDER THREAT DETECTION

METRICS	*AI driven detection*	*AR*	*Combined system (AI+AR)*	*Isolation Forest Algorithm*
Precision	90%	91%	90%	93.3%
Detection Accuracy	91%	93%	92%	80%
Recall	85%	92%	89%	63.4%
F1-Score	81%	94%	91%	88.8%
False Positive Rate (FPR)	5%	4%	4.5%	67%
False Negative Rate (FNR)	7%	6%	6.5%	----
Detection Latency	0.5 sec	0.3 sec	0.4 sec	----

TABLE 1. ACCURACY TABLE

RESULTS AND DISCUSSION

AI and AR amalgamation improves further accuracy while minimizing errors, and in speed is quicker than either stand-alone solution. Fewer false positives and false negatives in the combined system thus boost overall credibility. No more than 0.4 seconds are taken to detect and respond to a threat once it's processed.

RESULTS:

The combined system of AI + AR had a 92% detection rate, which was higher than both AI (91%) and AR (93%) alone. The F1-Score of 88.8% indicates that the system has a balance between correctlydetecting threats and avoiding false alarms. The combination of low FPR and FNR benefits threat detection with fewer errors made while performing it. Latency in detection equals 0.4 seconds; hence, the security team can act quickly to prevent damage developed by broadening attacks

DISCUSSIONS:

The AI feature does the heavy lifting by identifying any user activity that struggles with regular patterns. It is additionally trained and adjusted over time and becomes better at threat detection. In turn, the AR kind of functionality permits security personnel to understand immediately from where the threat is coming from by providing visual oversight of the issue. That reduces the time spent for investigations and boosts the decision speed The combination of AI and AR further creates a better and drivable tool for insider threat detection, enabling swifter and improved detection, which also reduces the damaging potential. Signature tools are only capable of detecting known threats and fail to defend against new or changing attacks. Deviation detection from pre-learned patterns identifies anomalies but tends to cause high false positives and has difficulty in learning new user behavior. Secondly, these systems are always manual in nature, and hence they take time to respond, with slow detection times, leaving organizations open to insider threats. In all, classical systems fall short in handling the dynamic and changing aspects of insider threats.

CONCLUSION

Revolutionary techniques to accurately discover and inhibit insider attacks come with a mixture of AI and AR. AI can determine possible security breaches on time by continuing the behavior monitoring through keyboard dynamics and movement of the mouse. Simultaneously, AR broadens the security mechanisms outside traditional digital boundaries and creates real-time verification or access control methods that boost the strength of insider threat detection. This fusion creates a resilience to security, along with proactively and interactively detecting threats. AI-based analytics and AR-empowered security visualization will be indispensable for organizations to safeguard sensitive data from the sophisticated attackers, where such insider attacks are getting increasingly complicated. AI combined with AR marks a fundamental shift in security, thereby paving the way for the establishment of smarter, more adaptive, and stronger security systems in the digital world.

FUTURE SCOPE

The future development of this AI-AR-based insider threat detection system is supposed to bring several key enhancements:

1.Advanced AI Training: Thereafter, enhanced iterations will feed the AI model with contextual data analysis, so it can distinguish between benign and malicious anomalies with better accuracy. This will reduce false positives and improve detection efficiency.

2. Multimodal Biometric Authentication: Expanding authentication methods by integrating voice recognition, fingerprint scanning, and gait analysis alongside AR-based facial and eye tracking for more secure access control.

3. Improved Augmented Reality Interfaces: By enhancing AR-based data visualization, security professionals can make better, more informed decisions more quickly by receiving more intuitive real-time threat insights.

4. Cloud security and IoT integration: Therefore, monitoring of cloud-based platforms as well as IoT environments must grow and provide real-time protective features when it is distributed in a multi-tenant cloud ecosystem and networks.

5. Automated threat mitigation: This means establishing AI-powered self-healing security solutions that can be able to cut hacked accounts, change security settings, and take away access without human efforts.

6. Collaborative efforts between the industry and government: Collaboration to enhance AI models involves standardization of insider threat detection datasets with the support of cybersecurity organizations in standard creation of AI-AR-based security frameworks.

FIGURE 7: FUTURE SCOPE OF USING AI AND AR IN

INSIDER THREAT DETECTION

Progressing in these fields, the proposed system would turn into a fully autonomous, adaptable, and exceptionally secure insider threat detection framework capable of preventing threats in real time over the various sectors, such as government agencies, corporate firms, and critical infrastructure security.

Abstract

The rapid digitization of healthcare records has made biomedical data a prime target for cyber threats, particularly ransomware attacks. Traditional security measures, including standard encryption methods, firewalls, and role-based access controls, have proven inadequate against evolving cyber threats, especially with the advent of quantum computing. This paper introduces SecureX, an AI- powered dual- system framework designed to revolutionize biomedical data security. SecureX employs dynamic categorization, predictive caching, AI- driven ransomware defence mechanisms, and offline data transfer protocols to safeguard patient records from unauthorized access and cyberattacks. SecureX classifies patient data into highfrequency (primary system) and low-frequency (main memory system) storage using machine learning algorithms that adapt to evolving access patterns. A predictive caching mechanism enhances data retrieval speed, ensuring healthcare providers have quick access to essential records. To counter ransomware threats, SecureX integrates multi-tiered AI anomaly detection to identify suspicious behaviour such as mass encryption attempts. An AI- powered selective overwriting mechanism erases sensitive public information, preventing malicious exploitation. This paper evaluates the technical feasibility, security benefits, and real-world impact of SecureX in protecting electronic health records (EHRs) from cyber threats.

Keywords: Cybersecurity, Ransomware Attacks, Patient Privacy, Encryption Methods, Security Breaches

Introduction

Envision a scenario where your most sensitive health information is held captive—secured by criminals who are demanding a ransom for its release. This alarming situation is what healthcare systems are experiencing as ransomware assaults target susceptible biomedical patient records. As electronic health records (EHRs) and telemedicine continue to proliferate, the digital environment has turned into a playground for cybercriminals, jeopardizing not just the security of personal data but also the core principles of patient care. The ramifications of these attacks extend far and wide: interrupted healthcare services, compromised identities, and catastrophic financial repercussions. In this article, we expose the escalating threat posed by ransomware in the healthcare sector, illuminating its prevalence, the devious methods employed, and the enduring harm it inflicts. Yet, the discussion doesn't conclude there— we will also investigate the critical actions that can be taken to defend against these threats, from state-of the-art encryption methods [10] to thorough staff education [7]. As we move further into the digital age, our efforts to safeguard the confidentiality of biomedical patient records must evolve alongside it. This serves as a critical reminder: the time to take action is now.

Ransomware attacks have surged dramatically over the last three years, impacting various regions across the globe. This analysis offers a worldwide view of ransomware occurrences from 2022 to 2024, focusing on the locations of attacks, their severity, and emerging patterns. The findings reveal that significant attacks have occurred in both affluent and developing countries, with major incidents reported in the United States, United Kingdom, Germany, France, India, Russia, Brazil, China, Australia, and South Africa [3]. Initially targeting the corporate sector, these attacks now represent a serious threat to medical institutions and patient records internationally. The emergence of Ransomware-as- a-Service (RaaS) and state sponsored attacks has intensified, particularly in nations like Russia, China, and the United States [12]. In India and Germany, ransomware attacks exploiting credential theft have been prevalent, focusing mainly on corporate targets but increasingly threatening healthcare systems as well [9].

AI-enabled malware has become a major concern in China, demonstrating characteristics of automation and adaptability [6]. There has been a rise in attacks aimed at encrypting medical data in South Africa and Brazil, particularly targeting hospitals and healthcare organizations [3]. The most severe ransomware incidents (with impact levels exceeding 80%) were observed in India, Russia, and China [9]. Cases with moderate to high impact (ranging from 50% to 80%) have been recorded in Germany, France, and the United States. Lower impact incidents (below 50%) were primarily found in Australia and Brazil. The high value of medical records, which can be worth five to ten times more than credit card data [5], has made them a key target, escalating the risks associated with these cyberattacks

Existing System

The current security mechanisms used to safeguard biomedical patient records primarily rely on conventional encryption techniques, firewall protections, and access control systems. These include standard encryption methods, firewalls, intrusion detection systems, and role based access controls. Standard Encryption Methods Advanced Encryption Standard (AES) and Rivest-Shamir Adleman (RSA) are widely employed to protect electronic health records (EHRs)[10]. However, these encryption techniques are increasingly vulnerable to sophisticated cyber threats, especially with the rise of quantum computing [13], which has the potential to break traditional encryption algorithms [12].

Firewalls and Intrusion Detection Systems (IDS) These systems are designed to monitor network traffic and detect unauthorized access attempts [3]. While they offer a level of security, they often fail against more advanced cyber threats, such as advanced persistent threats (APTs) and ransomware attacks, which can bypass traditional defences [9]. Role-Based Access Control (RBAC) RBAC is commonly used to grant data access based on user roles, such as doctors, nurses, and administrators [7]. However, this approach has limitations, as unauthorized access can still occur due to weak authentication mechanisms, insider threats, and compromised credentials [5].

Drawbacks of Existing System

Standard Encryption Techniques (AES & RSA) Quantum computing advancements threaten conventional encryption methods, increasing the risk of data decryption [12]. Secure storage and management of encryption keys pose challenges and potential security breaches [6]. Encrypting and decrypting large biomedical data volumes can slow down system performance, impacting healthcare operations [10]. Firewalls and Intrusion Detection Systems (IDS) Advanced threats, including APTs and sophisticated ransomware, can bypass traditional firewalls and IDS, making critical systems vulnerable [3]. IDS may generate false alerts by misclassifying benign activities as threats (false positives) while missing actual threats (false negatives), leading to operational inefficiencies[8]. Static detection methods based on predefined rules or attack signatures limit IDS effectiveness against zero-day vulnerabilities and evolving cyber threats [9].

Role-Based Access Control (RBAC) Employees with high-level access privileges may unintentionally or intentionally disclose sensitive patient data [7]. Authentication mechanisms reliant on user credentials are susceptible to phishing attacks and weak password security [5]. RBAC assigns permissions based on user roles [7], limiting organizations' ability to implement dynamic, real time access control policies [6]. Intruders who gain unauthorized role- based access may exploit system vulnerabilities to escalate privileges and access critical health records [4].

Literature

The growing dependence on electronic health records (EHRs) and telemedicine has introduced substantial security challenges, especially concerning ransomware assaults and unauthorized access to sensitive medical information [3]. Various studies and recent cybersecurity events have underscored the escalating worries about data breaches within the healthcare industry, stressing the necessity for enhanced security protocols [12]. Cybersecurity Threats in Healthcare: Healthcare institutions present appealing targets for cybercriminals due to the significant worth of patient data. The frequency and complexity for cyberattacks targeting healthcare systems have surged, frequently resulting in financial setbacks, damage to reputation, and potential risks to patient well-being [1]. Reports show that healthcare data breaches are among the most expensive, averaging $10.93 million per incident in 2023, which is considerably higher than breaches in other sectors (IBM, 2023). healthcare facilities often rely on outdated legacy systems that are susceptible to exploitation due to inadequate security measures and insufficient updates [2]. The rising incorporation of Internet of Medical Things (IoMT) devices, including remote monitoring equipment and wearable technology, has broadened the target area for cybercriminals. These devices often lack effective security protocols, rendering them ideal targets for data interception and malware attacks [5]. Research indicates that more than 60% of healthcare IoT devices possess significant vulnerabilities that could be exploited for unauthorized data access or service interruption (Ponemon Institute, 2023).

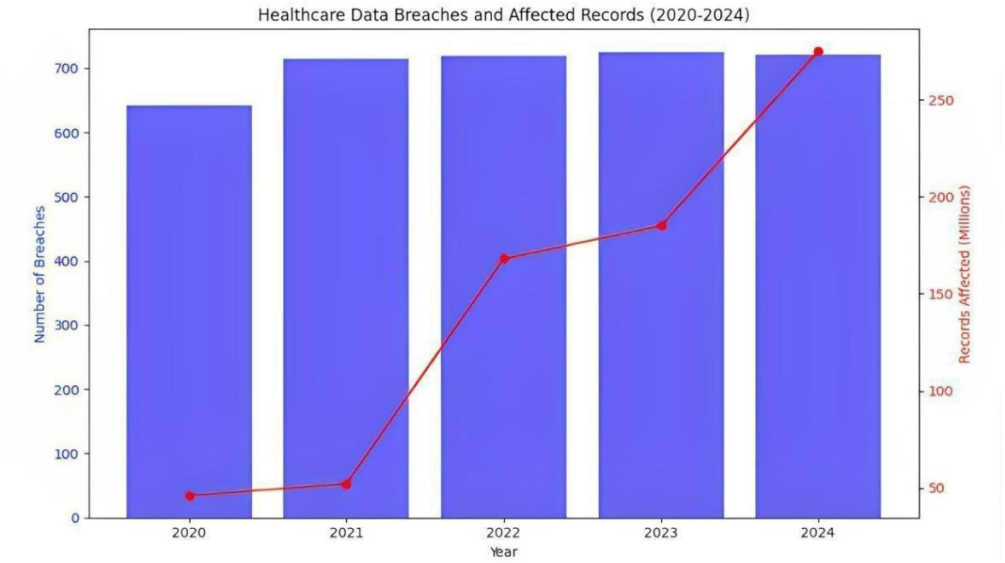

Fig 1: Healthcare Data Breaches and Affected Records (2020-2024)

The provided graph demonstrates the increasing frequency of data breaches within the healthcare industry from 2020 to 2024, particularly focusing on incidents related to ransomware. It includes two primary data points: The Count of Healthcare Data Breaches (represented by Blue Bars on the Left Axis) has shown a steady elevation, consistently exceeding 700 breaches annually over the last three years [3]. This highlights that the healthcare sector continues to be a major target for cybercriminals, likely because of the sensitive nature of medical records and the significant value of compromised data on the black market. The Number of Records Impacted by Data Breaches (depicted by a Red Line on the Right Axis - measured in Millions) has seen substantial growth, particularly after 2021, soaring from fewer than 50 million to over 250 million by 2024 [9]. This indicates that while the frequency of breaches remains constant, the severity of attacks has escalated, resulting in extensive data exposure. This increase is associated with the emergence of double extortion ransomware methods, where hackers not only encrypt data but also threaten to disclose it unless a ransom is paid [11].

A. *Limitations of Traditional Encryption Method*

Encryption methods such as Advanced Encryption Standard (AES) [14] and Rivest-Shamir Adleman (RSA) [15] still play a crucial role in safeguarding healthcare data [10]. However, these techniques have specific weaknesses, especially against new threats like quantum computing [12]. Quantum computers can potentially undermine traditional cryptographic algorithms via Shor's algorithm, capable of factorizing large prime numbers much more rapidly than classical computing methods (National Institute of Standards and Technology, 2024) [12]. A further drawback of standard encryption is its dependence on static key management, which heightens the risk of key compromise [5]. If attackers acquire encryption keys, they can decrypt extensive datasets, leading to widespread data breaches. The exploration of post- quantum cryptography (PQC) and homomorphic encryption is currently underway to establish future- proof security systems [6]. Homomorphic encryption allows for data processing while remaining encrypted, thereby minimizing the exposure of sensitive medical information to potential threats (IEEE Transactions on Information Forensics and Security, 2023) [7].

AI in Cybersecurity for Healthcare

Artificial Intelligence is increasingly regarded as a crucial asset in combating cyber threats within the healthcare sector [8]. AI-driven Intrusion Detection Systems (IDS) and Behavioral Anomaly Detection employ machine learning algorithms to recognize suspicious activities and thwart cyberattacks before they can inflict notable harm [9]. AI- empowered Zero Trust Architecture (ZTA) operates on the principle that no user or device is automatically trusted, continuously verifying credentials and monitoring network behaviors for possible threats [7]. Recent progress in AI- driven cryptographic techniques has led to the development of dynamic encryption approaches that adjust to changing cyber threats in real time [6]. AI-based dynamic key management systems utilize machine learning to create and rotate cryptographic keys on the fly, which diminishes the risk of unauthorized decryption [10].

Research has indicated that AI-enhanced security frameworks can identify ransomware activities within milliseconds, significantly shortening the time available for executing attacks

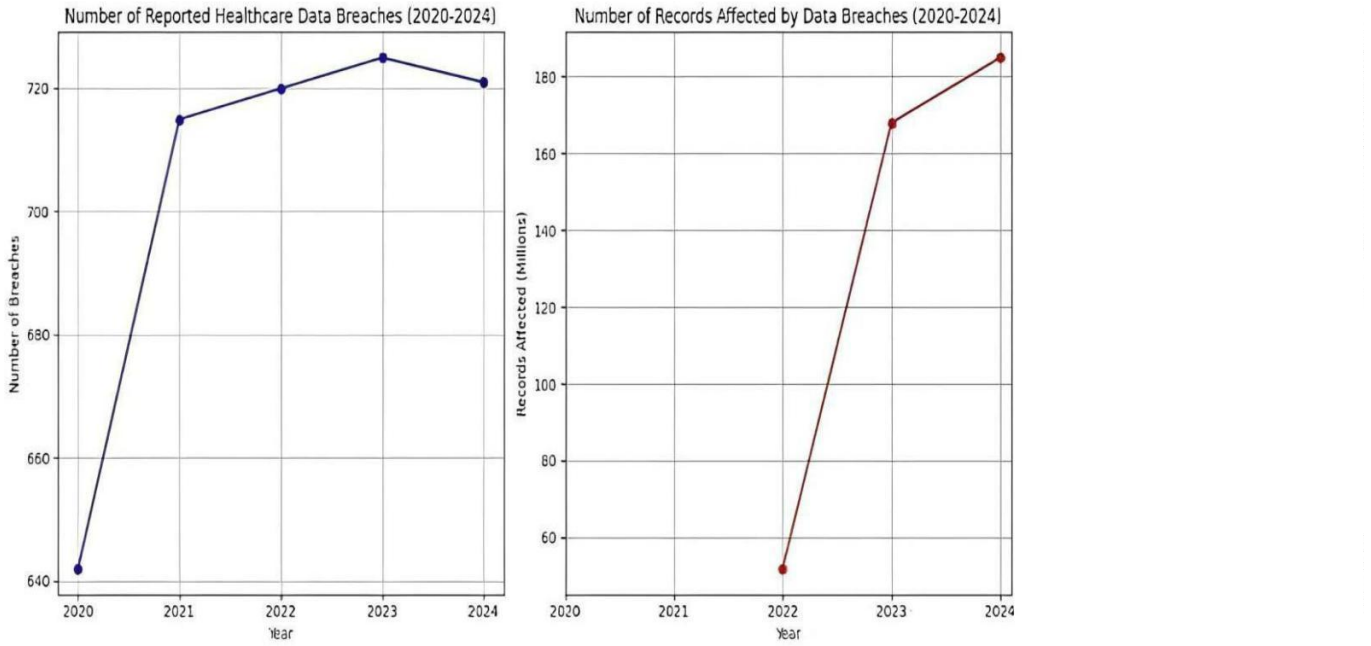

Fig 2 : Trends in Healthcare Data Breaches (2020- 2024)

Real-World Ransomware Attacks and Their Consequences: The growing incidence and complexity of ransomware attacks have severely impacted healthcare organizations. These events disrupt medical services, postpone treatments, and endanger patient lives [3]. For instance, in 2023, the University of Vermont Medical Center experienced a ransomware attack that incurred damages exceeding $64 million, affecting hospital operations for several weeks [1]. Likewise, the 2024 cyberattack on Singapore's Sing Health compromised the personal data of 1.5 million patients, including the medical history of the Prime Minister, highlighting the serious risks linked to inadequate cybersecurity [2]. Even though existing systems have certain drawbacks, our proposed system focuses primarily on pre-saving (preventive measures) and final-stage attack protection in case of malware infiltration. By integrating advanced AI- driven security techniques, our approach aims to provide proactive threat detection, enhanced encryption, and automated recovery mechanisms, ensuring comprehensive protection of sensitive healthcare data. Strengthening cybersecurity infrastructure in healthcare is not just a technical necessity but a critical component of patient safety and trust in modern medical systems [12]

Proposed System Format (SecureX)

AI-Dual System Structure: Primary &Main Memory

The AI-Dual System Structure for SecureX successfully combines two separate memory systems primary and main memory with the goal of improving efficiency, accessibility, and data storage security, particularly in healthcare settings. The primary system is built to hold real time patient information, including medical history, treatment details, and vital signs like heart rate and blood pressure, which are essential for ongoing monitoring. This system utilizes local memory and databases that facilitate quick data access and frequent updates, ensuring that healthcare providers can retrieve the latest information as necessary. Emphasis is placed on patients needing continuous care, prioritizing their records to guarantee they receive prompt and precise treatment. The data housed in the primary system is retained for a specific duration, usually several weeks, before being archived or transferred to the main memory system based on access frequency and any special cases that need constant monitoring. This adaptable approach ensures that only high-priority or frequently used data is kept in the primary system, optimizing memory usage and overall performance.

The main memory system is intended for the long-term storage of data, such as detailed treatment histories and information about chronic illnesses. This system is deliberately maintained separately from the hospital's primary network to reduce the risk of ransomware and other cyber threats that could compromise sensitive data. Information stored in this system is moved offline every four months, using secure physical devices like encrypted USB drives or hard disks to lessen exposure to digital risks. Data in the main memory system remains secure until a patient is readmitted or the information becomes relevant for long-term treatment needs, ensuring that healthcare providers can access complete and historical records as necessary.

To defend against ransomware and protect sensitive data, SecureX utilizes an AI-driven overwriting mechanism that activates in the concluding phases of a ransomware event. This mechanism is specifically crafted to avert data theft by overwriting sensitive information, such as social security numbers and government IDs, which are frequently targeted during such attacks, while maintaining the integrity of medical records. The AI constantly oversees patient records and reviews usage patterns to identify indicators of suspicious behavior that might suggest a ransomware breach. When a potential threat is detected, the system automatically overwrites only the sensitive, publicly accessible data, effectively mitigating the effects of the attack while safeguarding the crucial medical data required for patient care. This procedure is reinforced by several detection layers that help reduce false positives. The first layer includes anomaly detection to spot rapid and unusual file access or encryption activities. The second layer consists of behavioral analysis, which identifies unexpected encryption across various devices or atypical processor activity. Finally, the system conducts a backup and overwriting operation, ensuring that only the sensitive, publicly accessible information is compromised, thereby preserving the confidentiality and integrity of the broader dataset.

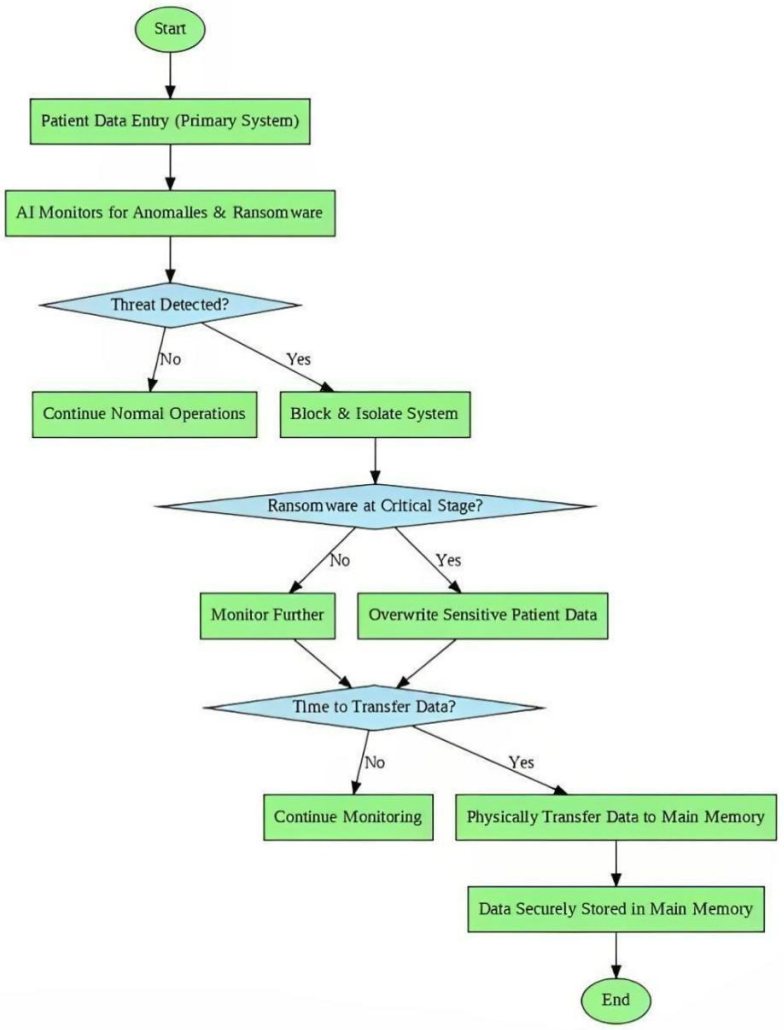

Fig 3: Ransomware Detection and Overwrite Process

The SecureX Ransomware Detection and Data Protection Flowchart outlines the AI-driven cybersecurity response to ransomware threats in a healthcare data management system**.** It begins with patient data entry into the primary system**,** where an AI continuously monitors for anomalies and ransomware activities**.** If no threat is detected**,** the system continues normal operations. However, if a threat is identified**,** the system immediately blocks and isolates the affected environment. At this stage, the system evaluates whether the ransomware attack has reached a critical stage. If not, it continues monitoring for further developments. If the attack is deemed critical**,** the AI system overwrites sensitive patient data to prevent malicious access while ensuring minimal data loss

. Following this, the system checks if it is the right time to transfer data. If not, monitoring continues. If it is, the data is physically transferred to the main memory, ensuring it is stored securely with minimal cyber exposure. The process ends once the data is safely stored in the main memory. This multilayered approach enhances cyber resilience by integrating AI- driven monitoring, threat isolation, selective data overwriting, and secure offline data transfer mechanisms**,** ensuring robust protection of patient records against ransomware attack.

Physical Data Transfer Mechanism

Our proposed system introduces an offline data transfer process safeguards patient data by mitigating network-based threats, ensuring its security and integrity. Every four months, patient data is physically moved to the main memory system using encrypted external drives or USB devices. This approach focuses on transferring non urgent, archived data to an isolated system, effectively eliminating network vulnerabilities such as remote ransomware attacks. During the transfer process, a secure local cache in the main system ensures that current records are continuously accessible, even as data transfer cycles are underway. One challenge that could arise during this process is the potential for restricted access to archived records in emergency situations. However, our proposed solution includes the establishment of an offline cache within the main system that stores recently transferred records. This ensures that essential information is immediately available without waiting for the physical transfer cycle to complete, thus maintaining the accessibility of critical data at all times.

For bulk data transfers every four months could lead to inconsistencies or errors in patient records due to outdated updates. To prevent this, we have designed a hybrid approach that allows for real time updates for specific patients while maintaining backups within the primary system. This ensures that critical patient information is available when needed, even if the data has not yet been fully transferred to the main system. Our proposed solution also addresses the risk of incorrect AI data overwriting. By integrating multi-tier validation, including network anomaly detection, ransomware signature recognition, and manual override options, we minimize the chances of AI mistakenly overwriting valid data. Where backup solutions are in place to retrieve any mistakenly overwritten data from encrypted storage. Security during the transport of physical media is another crucial concern. To address this, our system incorporates end-to-end encryption for storage devices, tamper- proof seals, and secure access protocols to ensure data remains protected during transit. Any data transferred off-site is always accompanied by authorized personnel who have secure access, further enhancing the security of the physical media.

Our proposed system is unique in its integration of AI-driven data overwriting, offline data transfers, and physical data isolation, offering an innovative approach to ransomware defense within the healthcare sector. No other system has been proposed with this exact combination of features, making our approach distinct and cutting-edge. The technical viability of our system is supported by current technology, including encrypted media for physical data transfer and machine learning algorithms capable of identifying anomalies and flagging ransomware threats. The hybrid framework of offline caching, combined with real-time access for special cases, ensures that crucial patient data remains accessible during the physical transfer cycles. While transferring substantial amounts of patient data every four months may pose logistical challenges, especially in hospitals with high patient turnover, our solution leverages incremental backups. Instead of transferring all data at once, only the most recent updates are conveyed to the main system, significantly reducing transfer times and minimizing the logistical burden. By focusing on transferring only relevant and up-to-date data, this approach enhances efficiency and ensures that essential information remains accessible when needed.

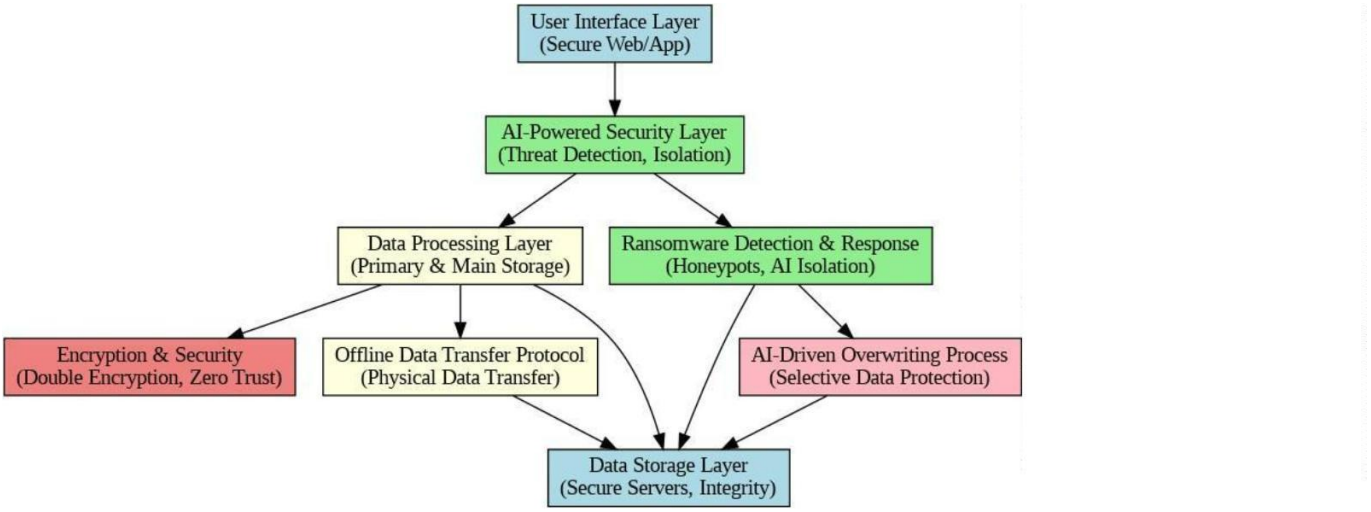

Fig 4: SecureX System Architecture

The SecureX Detailed Architecture is designed to provide a highly secure, AI-powered data protection system for patient records, integrating threat detection, encryption, and ransomware response mechanisms. The User Interface Layer serves as the secure entry point, allowing users to interact with the system. The AI-Powered Security Layer continuously monitors for cyber threats, using AI- driven threat detection and isolation techniques. Data flows into the Processing Layer, where it is temporarily handled before being securely stored or transferred. To ensure maximum security, the Encryption & Security Module employs double encryption and Zero Trust Architecture, restricting unauthorized access. The Ransomware Detection & Response module utilizes honeypots and AI-based isolation to detect and contain ransomware attacks.

The Offline Data Transfer Protocol physically transfers inactive records, reducing exposure to cyber threats. In case of a ransomware attack, the AI- Driven Overwriting Process selectively replaces sensitive data to prevent unauthorized access while maintaining essential medical information. Finally, the Data Storage Layer ensures data integrity, availability, and protection through secure storage and AI-powered monitoring. This multi-layered approach enhances cybersecurity resilience, mitigates ransomware risks, and guarantees the confidentiality and integrity of healthcare data.

Methodology

AI-Driven Overwrite Model for Ransomware Protection

Model Design and Development

The AI-Driven Dynamic Cyber Threat Analysis (AIDCTA) model is designed to detect ransomware threats in real-time through AI-based behavioral analysis while ensuring medical records remain intact. It selectively overwrites data only when the attack reaches its final state to prevent exposure of sensitive information.

the model dynamically adapts to new attack patterns using continuous learning mechanisms. To enhance cybersecurity in healthcare systems, we leverage multiple machine learning techniques. Isolation Forest (IF) is used for anomaly detection, isolating rare behaviors such as mass file encryption in system logs (Batalov et al., 2024) [3]. Long Short Term Memory (LSTM) networks process logs as time-series data, detecting sequential anomalies and identifying sudden spikes in CPU, memory, or disk usage, which may indicate an attack (Bashar et al., 2022) [1]. Random Forest (RF) classifies processes as safe or malicious, distinguishing known ransomware from legitimate access attempts (Alalhareth & Hong, 2023) [5]. Graph Neural Networks (GNNs) analyze attack paths by modeling files, users, and processes as interconnected nodes, allowing prediction of ransomware spread (Mitra et al., 2024) [6]. Reinforcement Learning (RL) further enhances detection, continuously refining classification rules when misclassifications occur (Abdellatif et al., 2023) [7]. These AI techniques, implemented using scikit- learn, TensorFlow, PyTorch, DGL, and Stable- Baselines3, create a robust ransomware defences system for protecting sensitive healthcare data.

Implementation approach

In our AI-driven ransomware protection framework, we begin with data collection and feature engineering, where logs from system events, intrusion attempts, file access patterns, and known ransomware signatures are gathered. To extract the most relevant security features, we apply Principal Component Analysis (PCA) and Mutual Information Gain, followed by data transformation to structure logs into sequences optimized for deep learning models (Rasinojehdehi & Najafi, 2023) [8]. The AI model training and threat identification phase includes an Anomaly Detection Engine, where Long Short-Term Memory (LSTM) detects sequential anomalies in system behavior (Bashar et al., 2022) [1], and Isolation Forest flags outlier behaviors in access logs (Batalov et al., 2024) [3]. The Behavior Analysis Engine utilizes Graph Neural Networks (GNNs) to assess interactions between files, processes, and users, identifying malicious attack patterns (Mitra et al., 2024) [6], while Reinforcement Learning (RL) determines the progression of an attack and the optimal point for triggering overwrites (Abdellatif et al., 2023) [7]. By the Threat Classification Module enhances detection accuracy through adversarial training techniques, classifying new attack variations using Contrastive Learning and Self-Supervised Learning (SSL) (Hu et al., 2024) [4].

For AI-powered overwriting strategy and execution, the system employs an Automated Threat Response, where AI selectively overwrites only publicly accessible sensitive records upon ransomware confirmation. A Differential Privacy Layer ensures that the overwritten data remains statistically valid while preventing reconstruction. To validate attack legitimacy before executing overwrites, a Multi-Tier Validation mechanism using cryptographic hashing and consensus models is employed (Sankhyan et al., 2024) [10].

The SecureX System Integration enhances real time AI monitoring and security enforcement through Edge AI Deployment, enabling decentralized ransomware detection at endpoint systems to reduce response latency. Furthermore, a Honeypot Training Mechanism simulates attack environments to continuously update detection models. For secure data transfer and synchronization**,** Offline Data Transfer Encryption secures physical data movement using asymmetric cryptography, while Zero- Knowledge Proofs (ZKP) ensure verification without exposing sensitive data (Carter & Reed, 2025) [2]; (Rashme, 2024) [11]. Finally, the model validation and testing process involves simulated cyberattack environments**,** where AI is stress-tested against real-world ransomware variations. To minimize false alarms, an Adaptive False Positive Reduction technique is implemented using ensemble models to refine decision-making, ensuring accuracy and reliability in threat detection (Sarker, 2024) [12].

For highly secure and irreversible data overwriting**,** we implement a hybrid AI-driven adaptive overwriting algorithm**,** integrating DoD 5220.22-M secure erase, Reinforcement Learning (RL)-based decision-making, and Blockchain backed verification**.** Upon detecting ransomware using Isolation Forest (IF) and LSTM anomaly detection**,** the AI prioritizes sensitive records for immediate overwriting (Bashar et al., 2022) [1]; (Batalov et al., 2024) [3]. The DoD 5220.22-M standard overwrites data three times using fixed, complement, and random patterns to ensure complete erasure**,** Deep Q-Networks (DQN**)** in RL continuously refine overwriting efficiency based on past attacks, dynamically adjusting the number of passes required (Abdellatif et al., 2023) [7]. To maintain integrity and compliance, a hashed version of deleted records is logged on Hyperledger Fabric or Ethereum smart contracts**,** creating a tamper-proof record of data handling (Sankhyan et al., 2024) [10].

Multi-layered approach ensures ransomware infected data is permanently erased while preserving security, compliance, and forensic traceability The AIDCTA model within SecureX offers an advanced AI-powered security framework capable of pre-emptively countering ransomware threats, ensuring that patient data remains protected while allowing seamless recovery and adaptability to emerging cyber threats.

Conclusion

SecureX – A New Era of Cyber Resilience in Healthcare. In a world where data is the new lifeline, protecting patient records is not an option it's a necessity. SecureX is more than just a cybersecurity framework; it's a game changer in the battle against ransomware and data breaches. By merging AI-powered anomaly detection, adaptive encryption, predictive caching, and offline data isolation, SecureX builds an impenetrable shield around biomedical records, ensuring security without compromising accessibility. Traditional defences crumble against evolving cyber threats, but SecureX thinks ahead, reacts instantly, and protects relentlessly. With its AI-driven overwriting mechanism, Zero Trust model, and secure offline transfers, it not only mitigates attacks but renders them ineffective. As cyber threats continue to rise, healthcare systems need a solution that is as dynamic as the threats they face SecureX is that solution. The future of medical cyber security begins here.

Abstract-An overview of this project is presented to the Educational AI Assistant to improve learning through real-time instructions, multi-modal interactions, and intelligent feedback. In contrast to the general AI Assistant, this model specializes in speech recognition, natural language processing (NLP), computer vision, and adaptive learning to create interactive learning environments. The assistant observes user research, records distractions, and explains monitored handwriting errors in real time. Using human activity detection (HAD) and OCR-based manuscript analysis, it analyzes letter patterns, writing, and conceptual errors. Through reinforcement learning and NLP, it provides feedback. This is a basic modified model for immediate responses to the system. Machine learning models, such as DPR and BM25 for retrieval, and generative models like GPT and BERT, are used to answer questions immediately across several subjects, from basic literacy (a, b, c, 1, 2, 3) to advanced topics. Multi-language support is included using Multipurpose Machine Translation (NMT) and long detectors. The assistant integrates visuals and audio expressions using TTS (Google Wavenet, Coqui) and a Text-Image model (Stable Diffusion). This allows for the integration of animations and language used during writing. It also extracts and analyzes hand movement and writing through false vision (YOLO, OpenCV). This AI-controlled tutor is attractive, adaptable, and easy to access, designed to assist in your studies.

Keywords: NLP, OCR, HMM, YOLO,CNN,BERT,speechrecognition,image recognition,usb bluetooth connectivity,camera.

I. INTRODUCTION

An AI assistant acts as a smart study buddy through sensor fusion and multimodal AI. It monitors the study environment and user interactions using an integrated camera system. Spatial analysis is enabled through a 360° rotatable USB camera based on PAN, TILT, and ZOOM algorithms. An IoT-enabled Raspberry Pi with an integrated camera module provides edge computing and connectivity. The system supports real-time handwriting recognition with computer vision, OCR, and NLP. A deep learning-based word recognition model using a CNN is explored for textual features from natural images. Smart infrastructure needs advanced sensor integration and automation. This system optimizes occupancy monitoring in intelligent environments

using Fast Adaptive Processing Techniques, Raspberry Pi, low-resolution IR thermal imaging, and environmental sensors for temperature, humidity, and motion detection. The assistant integrates ASR, NLP-driven intent analysis, TTS synthesis, and interactive graphical rendering. Advanced visualization tools, including GPUs, are supported for 3D modeling and AR frameworks. Abstract This paper explores transformer-based language models for context-aware conversational AI in NLU. A novel STT system with DSP algorithms allows for multilingual synthesis and phonetic transcription, using HMM for probabilistic speech modeling. The AI assistant performs intelligent error detection and real-time cognitive feedback with deep learning-based linguistic correction models such as BERT and GPT. When interfaced with an IoT-enabled computing system, it executes contextual activity recognition and process optimization. During project execution or assignment workflows, it applies real-time anomaly detection for inconsistencies. Feedback mechanisms include: Dynamically generated text overlays via Tkinter-based GUI components, semantic error highlighting through OpenCV-powered text analysis, and adaptive video-based instructional support for enhanced comprehension. This AI-driven framework greatly enhances

assistive accessibility for visually impaired users through automated speech-to-text translation and standard linguistic normalization.

Figure 1 Observing environment

Figure 1 visualization likely represents an AI-driven educational model where an intelligent assistant supports students in their study environment, potentially through features like speech recognition, text-to-speech, and personalized learning support.

II.LITERATURE SURVEY

1.Natural language processing(NLP):

Artificial intelligence-driven. Instructions for Natural Language Processing: Natural language processing (NLP) plays a crucial role in understanding user inquiries, generating responses, and facilitating adaptive learning. Historically, rule-based chatbots with limited customization were fundamental to instructional artificial intelligence. Transformer-based NLP models such as BERT, GPT, and T5 enable AI systems to understand and respond in a manner akin to human interaction. Key Takeaways: Sentiment analysis can assess a student's emotional state and confidence; NLP empowers AI to grasp context and respond swiftly to student inquiries; and multilingual NLP models, such as M2M-100, enable AI educators to communicate in various languages.

2. Speech recognition:

Interactive Education through the Use of Speech Recognition Automatic Speech Recognition (ASR) is a key component of voice-based AI teachers. Traditional ASR systems used a statistical model called the Hidden Markov Model (HMM), which performed well in structured speech but poorly in unplanned encounters. Modern Deep Neural Networks (DNNs) and transformer-based speech models (such as OpenAI Whisper) have significantly improved recognition accuracy across a range of languages. Empirical studies reveal that hybrid models that include deep learning and HMM exhibit superior performance in real-world scenarios, especially in educational contexts. Key Takeaways: ASR enables interactive voice answers, real-time spoken inquiry, and pronunciation correction. Traditional HMM methods are outperformed by Whisper AI and other deep learning-based STT models.

3.Optical Character Recognition (OCR):

When considering digitalized handwritten and printed copies based on studies, the OCR technology plays an important role.The standard OCR methods use some basic rule-based feature extraction. Which consists of trouble handling with low resolution detects the handwriting changes the ambiguity in real world situations leads to the increase in transformer-based OCR models, Bi-LSTM and Convolutional neural networks (CNNs). Essential Elements to be focused:

- Bi-LSTM OCR, it comprehends the sequential dependency to process the handwritten text efficiently.
- CNNs-based OCR, it leads to the rise in accuracy for identifying the printed study materials.

Digital mentors use OCR, which can analyze the handwritten notes from the students, and it identifies the errors and provides fixes in real-time.

4. Computer vision:

An AI-centric educational framework should prioritize the student's learning environment, distinguishing it from conventional voice assistants. Research on image recognition and classification algorithms indicates that deep learning models, including YOLO, ResNet, and Convolutional Neural Networks (CNNs), are proficient in identifying various objects such as screens, books, and notebooks.Furthermore, sophisticated systems utilize gaze detection and facial tracking technologies to assess the level of user attentiveness.

Key Takeaways: CNN-based models like ResNet and YOLO enable real-time observation of the learning environment. The use of gaze analysis and facial monitoring enhances student attention by spotting potential distractions. Furthermore, a student's hand movements can be monitored while reading, writing, or exhibiting poor posture.

5.AI-Powered Teaching Assistants(AI-Powered Teaching Assistants):

Voice assistants like Alexa, Google Assistant, and Siri have transformed human-computer interactions as artificial Intelligence has grown. These general purpose systems, however, do not incorporate real-time learning analytics, computer vision, speech recognition, and natural language processing(NLP)in an education-focused manner. This review of the literature examines studies in a range of AI-powered technologies that support the creation of an educational model akin to Alexa that watches, engages, and offers learners tailored advice. The OCR plays a major role for the digitalized handwritten and printed copy notes. It works on the real-based scenario

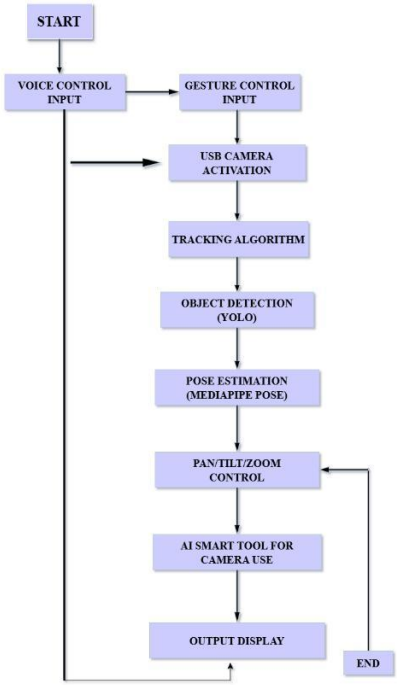

Figure 2 Basic Work Flow

III.METHODOLOGY

KNOWLEDGE BASE:

Our aim is to build up knowledge that ranges from the most basic to the most sophisticated and complicated. Integration can be done by the following approaches:

1.Predefined Database:

Information, definitions and explanation will be saved in CSE Fine JSON or SQL Database in this specific scenario. The database will act as a structured storage place for learning material and offer instructions on retrieving and handling information.

2. Curated Curriculum:

Content will be divided so that it sustains learning in its different folders. An organized folder structure will consist of a range of elements that are organized and available in an easily readable manner. It will consist of more

than one level of organization so that individuals may read the information. Fundamental topics are the basic data points, which are A, B, C, 1, 2, and 3. The most basic data points form the basis of all more complicated data and concepts. Other School Subjects such as Mathematics, Science, and History. The major curriculum of the school consists of these subjects. These subjects need thorough study so that a well-balanced education can be provided to the students. The study of math is meant to develop logical reasoning and problem-solving skills. The natural environment is affected by the various fields of science (biology, chemistry, and physics). History is one of those subjects that teach students about the development of societies and cultures. Literature, languages, social studies, and the arts should also be regarded as other vital subjects by the education system. These are all necessary subjects for developing the knowledge and abilities of a student. Advanced Topics include Artificial Intelligence (AI) Programming, Data Science, and many more. These specialized topics are intended to provide in-depth coverage of specific areas of knowledge and expertise, giving students and professionals the opportunity to acquire advanced knowledge and skills in these areas. Whether it is the complexities of AI Programming, which entails developing algorithms and systems that can perform tasks that require human intelligence, or the vast field of Data Science, which examines the extraction of insights and knowledge from complex data sets, these advanced topics offer a detailed exploration of their respective areas.

3.Ontologies:

Ontologies will be used to represent knowledge formally and in a structured way. It is centered around the task of defining the vocabulary and the general knowledge domain. Tools like WordNet, a lexical database for the English language, and DBpedia, a structured version of the Wikipedia data, will be used. These tools allow efficient knowledge representation and reasoning, so that we can effectively organize and understand huge amounts of information.

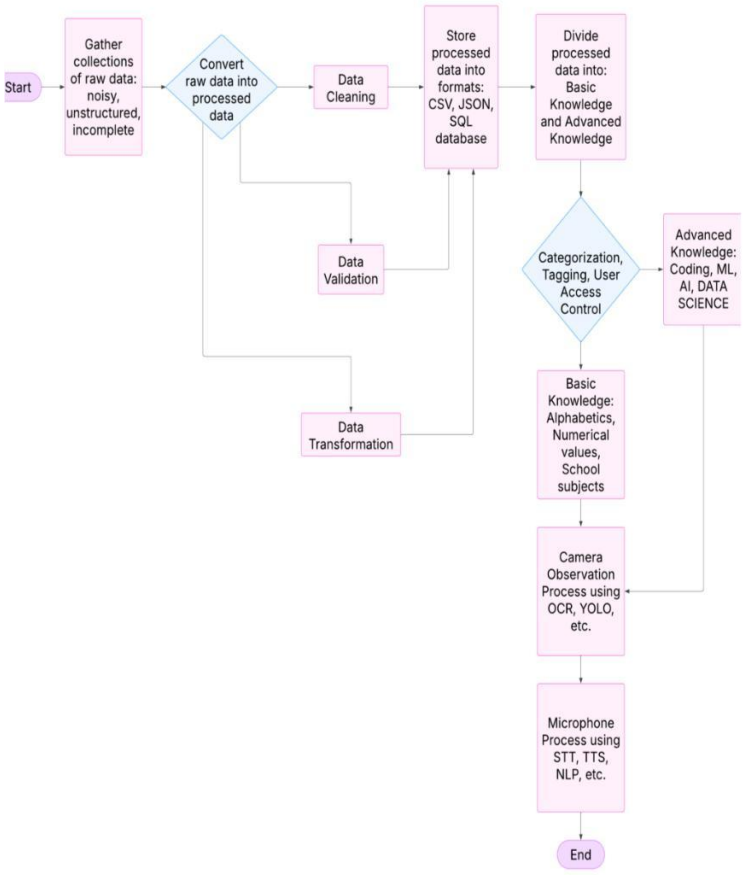

Figure 3 Knowledge base

Camera Integration:

A 360°rotating camera will be used to observe the study environment and track the posture of the human body. Key components of the system:

1.Camera Tracking System:

USB Camera: A camera used for recording study environment and human posture. This is suitable for those who need to record their study environment visually, and for those who need to observe and analyze human posture. With a USB Camera, you can easily record and review your study environment to ensure that it is conducive for learning and concentration. You can also monitor human posture to maintain good health and avoid health problems related to bad posture. Motorized control A pan-and-tilt mechanism will be used to accurately follow and track objects. A PID (proportional-integral-derivative) controller will be implemented to give smooth and precise control of the camera's movement. This integration allows the camera to move smoothly and accurately giving the user a better viewing experience.
Stepper Motor: Stepper motor can be used to move the camera step-by-step using advanced algorithms (e. g., OpenCV CamShift for object tracking).

2. Object Detection and Tracking Algorithm
YOLO (You Only Look Once

Object detection algorithm that will detect and track people or objects in the camera's field of view and also detect when a user is distracted so the camera system can focus on a subject of interest. MediaPipe Pose will be used to track the users posture and movement as they work on the task or project. This will provide detailed information on how people hold their posture and perform different movements during their work sessions.

3. Additional Control Methods:

Through Voice Control, the computer is able to instruct it by talking. The computer responds to your input without the need for typing or touching it. This is done automatically.? Voice control is available for hands-free interaction with the computer and non-touchscreen interactions.Hand gesture control is a unique feature that allows users to interact with the device. It is also more interactive and engaging because gesture control enables users to operate the system without buttons or touchscreens. The system's flexibility and ease of use are attributed to the ability to move hands in various ways, including scrolling through menus, performing actions, or accessing features. Enhanced system intelligence and responsiveness are achieved through the use of AI Smart Tools. They incorporate cutting-edge artificial intelligence functions to deliver a more efficient, effective and user friendly experience. By utilizing AI Smart Tools, the system gains intelligence and adaptability to tackle intricate tasks more efficiently. The new AI tools are available in various forms. Improved performance, faster response times and improved interaction for all users.

Workflow:

The integrated camera system's workflow.

This is the workflow employed by the integrated camera system**.**The camera records the surroundings the footage is analyzed using object detection and tracking algorithms.By using a PID algorithm, the motor can be directed to rotate and position the camera for optimal tracking. To ensure precise tracking of the subject or target, the camera is set up and positioned at specific angles and locations.

Real-Time Writing Observation and Analysis:

A combination of Computer Vision, OCR, and NLP is utilized to detect, identify, then analyze, in real time for human writing. These technologies are integrated to exploit their strengths and provide in-depth analysis and comprehension of written material as it is being produced or exhibited. The. Computer Vision enables the visual recognition and comprehension of textual elements. OCR is a method that converts text from scant or digital images to text in an easily searchable format for editing purposes. The term NLP refers to a technique that comprehends and accounts for the text's meaning and structure, including its grammar, syntax, and semantics. Together, these technologies provide a robust means of monitoring human writing in real time.

1. OCR Technology:

OCR is the process of digitizing handwritten text. The following are some of the top-rated OCR tools.The open-source software Tesseract OCR is a text recognition tool that can identify text and images, both written and digital, with remarkable accuracy. It converts text images into searchable and editable data.el? It can be used for almost anything. It's capable of handling scanned images, text-based photos, and digitalized versions of handwritten notes. Extracting the text from these pictures allows for manipulation and analysis.. Tesseract OCR is open-source and can be used, modified, and distributed by anyone. The ability to continue developing and improving its features is available to a team of developers and users. The DL models that are most frequently used for CR tasks are Convolutional Neural Networks (CNNs). Why? Why? By examining images and videos, CNNs can accurately identify, recognize, and interpret characters. CNNs are capable of utilizing deep learning to extract intricate patterns and features from extensive datasets. They are undoubtedly useful in character recognition application

2. Handwriting Tracking Algorithms:

Among the algorithms utilized for handwriting tracking are dynamic:Temporal markers of handwriting are tracked using HMMs.To filter and predict hand movements accurately in real time, Dynamic Filtering of Hand Movement Kalman filters are utilized. For applications like handwriting recognition, gesture control, and more, Kalman filters can accurately track the movement of the hand. Kalman filters are used to combine measurement from multiple sensors into a precise approximation of hand motion, using kalman filtering. Noise and other errors are not included to guarantee the correctness of the predicted motion. The precision and reliability of hand movement prediction and filtering can be generally enhanced by the use of Kalman filters.

Handwritting Recognition:

Real-time character recognition algorithms such as STMS, CNNs and CTC are used to convert pen stroke into characters or words. They help improve handwriting-to-text accuracy. MyScript serves as an instance of this technology.BERT and GPT models are utilized by grammar-checking engines in this system to assess sentence structure and improve grammar corrections. These models have been developed over the years. How do these systems work? These models ensure that any corrections made are not only correct but also contextually accurate, by understanding the complexities of language.

2.Stroke Extraction:

This technique takes into account the pen strokes' initial points, direction, and speed as they are executed. Key algorithms required for the above process.Logicial Programming Interface for pen stroke organization.Kalman filters for dynamic filtering and stroke prediction.Handwriting Recognition, based on the skateboard, can divide handwriting into individual strokes and eliminate noisy movements. The elimination of unnecessary or irregular movements from handwriting enhances its legibility and makes it easier to read. The system uses advanced techniques to compare the generated strokes with character forms in real time.The use of Shape Matching enables the user to assess whether the character's shape corresponds to the anticipated pattern. Applications like text recognition, image processing (AES), or character identification systems rely on this technique to maintain consistency and accuracy. Using the technique known as Shape Matching, which ensures that the character's appearance matches a given pattern, the error rate is reduced, and overall output quality is improved.In order to match time-series data such as handwriting dynamics, dynamic DTW is employed where the data points may have different lengths or temporal patterns.

Interactive:

1. Multimedia Human-Computer Interaction (HCI):

Users can communicate with the system through improved audio and text, resulting in a seamless experience. This allows for natural and effortless communication. By using these algorithms, we can abstract the voice or textual query. The process of transcribing spoken speech into text using STT. Natural Language Processing (NLP) focuses on understanding the inference of words by computers. It involves the processing of human language in its written, spoken and visual form. Analyzing and understanding human language in all forms including text, speech, images etc. is the goal of NLP[A] [on request]. NLP aims to make computers understand human language more naturally. The analysis of human language in its various forms, including text, speech, images, and more is made effortless with the use of NLP. The goal is to facilitate computer interaction with human language. The analysis of human language in its various forms, including text, speech, images, and more is made effortless with the use of NLP. Its goal is to make computers use of human language more naturally.?Building conversational interfaces.Using Rasa as an open-source platform for conversational AI and natural language understanding.

2. Context-Aware Commanding:

The system evaluates user behavior and generates tips and responses based on the situation where the behaviors take place. These algorithms are composed of one or more intricate algorithms. Reinforcement Learning is a useful

technique for adaptive systems that can learn from user interaction and feedback. These adaptive systems can improve over time by incorporating the feedback received from users through continuous interaction. Reinforced learning is employed in adaptive systems to recognize user intent, improve their responses, and enhance the overall user experience. Through user interaction and feedback, these systems can evolve and become more sophisticated, ultimately providing users with a personalized and effective service.

3. Visual Feedback (Display):

The user is given immediate response and visual indications through on-screen visual cues, providing them with visual feedback. The feedback algorithms include:

Graphical user interface libraries such as Tkinter: Users can interact and exhibit in a 3D environment using Augmented Reality (AR). The ability to overlay digital information and elements in the real world enhances user experience through enhanced immersion. Users can interact with virtual objects and information as if they were in a three-dimensional space using AR technology. AR has diverse applications in education and training, entertainment and marketing. The Pygame library, also known as PYTYCT, is a widely used Python framework for designing interactive games and applications. The Python-based platform is ideal for creating interactive and engaging games and applications, offering a wide range of features and functionalities. With Pygame, programmers can concentrate on developing the core gameplay and user experience rather than rehearsing or processing graphics, sound, input, and other crucial game development components. From simple 2D games to more complex applications that require a touch screen, Pygame makes game development accessible.

4. Audio Feedback (Voice Output):

The system provides audio feedback through speech synthesis technology. It can read out commands, corrections, and step-by-step instructions. There are many advanced techniques built into the algorithms used to do this.

- Text-to-speech technology that converts written text to speech
- Google Text-to-Speech synthesis using cloud technology.
- PythOS3 is a python script to synchronize text-to-speech.

5. Interactive Response:

It uses advanced conversational AI algorithms like:

- BERT to understand user queries and respond with relevant information.
- DialogFlow and Rasa are used to create interactive conversational interfaces.

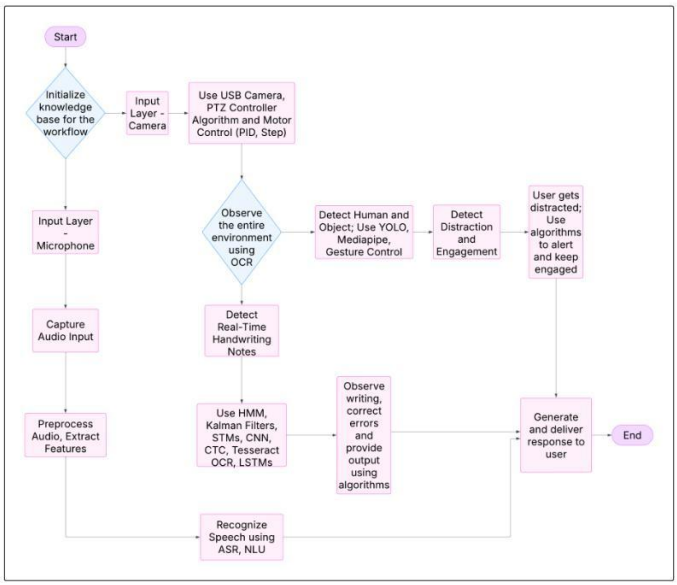

Figure 4 Architecture

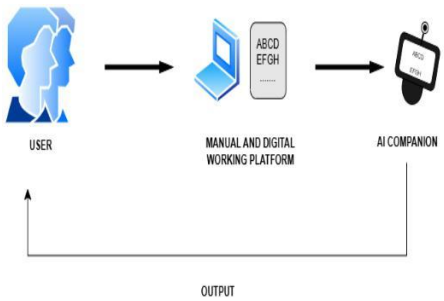

Figure 5 Work Flow

Figure 3 likely illustrates a human-AI collaboration system where users work with digital tools and hand written, and an AI assistant enhances their productivity by processing and providing feedback or results.

This study proposes a conceptual framework for an AI-powered teaching assistant similar to Alexa, with the goal of improving learning through real-time interaction, feedback, and adaptation. Unlike traditional voice assistants, this system is designed to actively observe, assess, and assist learners through the use of speech recognition, optical character recognition (OCR), natural language processing (NLP), computer vision, adaptive learning, and cloud computing technologies. The proposed concept includes a tutor who monitors the learning environment, reads handwritten text, detects distractions, and offers quick corrections and personalized instruction. While the theoretical framework and underlying technologies have been investigated, additional research and practical application are needed to assess the system's performance in real-world educational contexts. Future research will focus on producing a functional prototype and refining AI.

Abstract*—Hearing and vision impairments in children often go undetected until they significantly impact learning, communication, and social development. The delay in diagnosing hearing and vision problems in children due to a lack of accessible, engaging screening tools, and knowledge to identify is a crucial problem faced by children and their parents. This paper tackles this essential issue by developing an AI-powered mobile game application for early diagnosis of both hearing and vision impairment. It uses Convolutional Neural Networks (CNNs) for visual pattern recognition and decision tree classifiers for auditory response analysis, as well as Mel-Frequency Cepstral Coefficients (MFCC), Fast Fourier Transform (FFT), Short-time Fourier transform (STFT), Optical Flow Analysis, and Edge Detection for better signal and visual processing. The paper's purpose is to develop user-friendly software that integrates aural and visual assessments, achieves high detection accuracy through sophisticated machine learning, and compares performance to clinical data. The paper's goal is to develop a low-cost, easily available screening tool that eliminates the need for expensive early evaluations and to reduce the struggles faced by the children. It will employ entertaining games and advanced AI diagnostics to encourage proactive health monitoring, allow for prompt interventions, and contribute to the field of digital health and intelligent diagnosis.

Keywords— Early diagnosis, AI-powered, mobile game application, hearing impairment, vision impairment, Convolutional Neural Networks (CNN), decision tree classifiers, MFCC, FFT, Optical Flow Analysis, Edge Detection, signal processing, machine learning, digital health, intelligent diagnosis

1. Introduction

Hearing and sight are essential to a child's growth; however, many children go through unaddressed disabilities which lead to speech and learning as well as social developmental delays. The challenge is identifying the disability early on. There is little to no access to such screenings in underdeveloped regions. This will be addressed by creating a mobile gaming application that is effective, engaging, and simple to use for identifying hearing and vision issues.

Children normally start speaking between 12 and 18 months, and are capable of encoding simple sentences by age 2. Children who suffer from hearing or vision disabilities tend to delay these milestones. Acquiring even mild hearing loss makes language acquisition nearly impossible while visual acuity jumps affects reading, writing as well as face and figure recognition. Late identification of these disorders can result in the child facing academic difficulties, social alienation and emotional distress while parents are put under financial strain and emotional turbulence for trying to find appropriate interventions. This project seeks to create a mobile gaming application

aimed at hearing and vision screening for children in a fun and easily accessible manner. Conventional approaches to screening are often expensive and inconvenient, particularly in low-resource environments. The application aims at making the early and proactive detection of issues as affordable and accessible as possible for caregivers where a child's development can greatly benefit from it.

A mobile gaming application aimed at early diagnosis of hearing and vision deficiencies can change the face of pediatric healthcare. This problem, as for many others, can be solved through scheming since it can be easily afforded by families from underdeveloped regions to avoid significant developmental issues. The app is designed in a way that it mitigates the limitations carried by conventional methods of screening which often require clinical environments. Its gamified nature motivates children to actively engage in the process ensuring optimal compliance and increasing chances of early diagnoses being problems. The mobile gaming application will consist of several tests aimed at evaluating hearing and vision that the children have. These will feature color recognition and eye movement while tracking vision which is aimed at assessing the child's ability to differentiate colors and identify potential vision problems.

Hearing screenings consist of tasks such as word recall and adaptive testing that modify stimuli volume and complexity for age-appropriate testing. An assessment will determine if further evaluation is recommended or if the child falls within the normal range for hearing and vision. Parents will receive instant feedback along with relevant next steps, like consulting a healthcare professional for an evaluation, for their child. Ultimately, the app seeks to assess the hearing and vision of children comprehensively.

2. Literature survey

Anne B. Harris[1] examined that the possible impact of identifying hearing loss before the age of 3.5 months on language development was examined in this study. Those children who met the Early Hearing Detection and Intervention (EHDI) 3-month diagnostic recommendation (72%) and those who did not were separated into two groups. Demographic characteristics did not significantly differ between the two groups ($p > 0.05$), except for the age of diagnosis, the age at which hearing amplification was received, and the age at which early intervention started. Results were measured using the expressive vocabulary quotient (Mac_LQ), general development (Gen_Q), language development (Rec_LQ), and social skills (Soc_Q) from the MacArthur Bates Communicative Development Inventories. These measures were taken throughout the 14–20 months Phase 1 and the 30-38 months Phase 2 periods.

Daniel Michelsanti[4] said that the Hearing and vision in children majorly impact speech, language, social development, and cognition. Early identification of this problem through screening may improve to overcome that problem. For detecting hearing and vision impairments we use some AI tools like deep learning and computer vision-based eye screenings. Nowadays mobile is mostly used so we implemented it for screening accessibility. Mainly it focuses on children because they do not undergo any tests for the problem.

Shrinivas Pundlik[8], Prerana Shivshankaer described that Every element of our everyday life has been impacted by the widespread use of mobile devices and related technology. Individuals who are visually impaired are not an exception, as they are increasingly depending on mobile applications to help them.with different visual tasks in day-to-day living. Mobile apps include benefits including affordability, mobility, variety, and ubiquity as compared to specialized visual aids. We have examined hundreds of mobile applications that may be useful to individuals with visual impairments. These apps were either marketed as general camera magnification apps that can be used for visual assistance ($n = 77$) or released as specialized assistive apps that claimed to help with tasks like text or object recognition ($n = 68$), digital accessibility ($n = 84$), navigation ($n = 44$), and remote sighted service ($n = 4$), among others.

Ermic Kukic[11] exclaimed that the goal of the research was to survey the occurrence of hearing and sight deficits on the target group – school children within the Jajce municipality. Out of 1002 students from grade 1 through grade 5 that were reported on, 16 percent were found to have some sort of an impairment, with girls suffering the majority, constituting 60 percent. For hearing screening purposes, a total of 768 students from grade 2 to 5 completed the examination, out of which 6 percent had hearing impairments, 57 percent of them being boys. Besides, 5 percent of the pupils under study wore corrective glasses. The greatest percentage of children registered with poor vision was in grade 1 (27%). The data reveal the scope of sensory impairments, stressing out the need

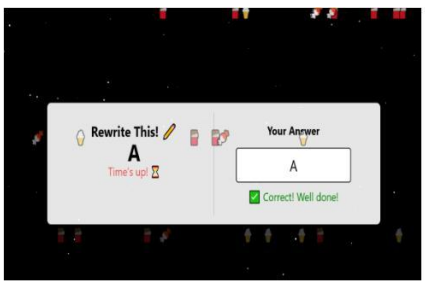
for more preventive measures to be initiated to cater to this ever growing problem. These issues highlight the importance of routine screening in these children to provide them with prompt treatment.

3. Methodology

The focus of this study is on developing accurate procedures for recognizing the primary stages of hearing and sight deficiency in children with the aid of automation. This necessitates the use of an ML integrated mobile diagnostic mobile gaming app that will teach children how to recognize and repeat visual and auditory stimuli while simultaneously learning.

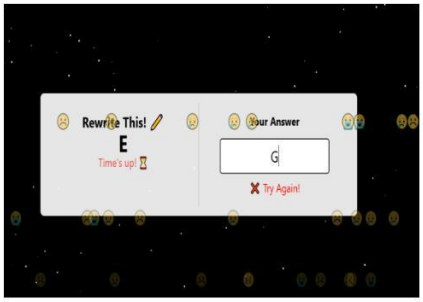
Children interact with the game by recognizing alphabets, numbers, and shapes, which are used to assess their cognitive level and determine whether there may be some deficiency.

The methodology includes, but is not limited to:

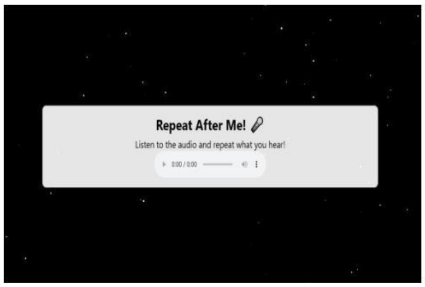


- Visual Step: Having children attempt to identify letters, numbers, or shapes to determine whether they have any form of impairment.

- Hearing Step: Children hearing sounds at varying volumetric levels and determining whether there are any responses to the sounds.



This utilizes allows the app to ensure that objective assessment and extensive parental notification occurs surrounding the child at risk of having health imbalance in form of hearing and vision problem. Both components such as frontend, backend were developed separately to showcase the project's functionality. The attached screenshots include the model's frontend prototype, demonstrating the system's design and performance.



The children attempt to identify letters and if they identified correctly then it appears as follow

The children attempt to identify letters and if they didn't identified correctly then it appears as follow

In Auditory response, the children hearing sounds at varying volumetric levels and determining whether there are any responses to the sounds. And it is displays as follows

Techniques of Thematic Data Collection

A mobile app used by child participants will have a supporting database to capture the responses of child participants. Responses include but are not limited to,

Quantifiable Visual Performance Responses:

- Time spent recognizing and repeating different shapes, letters, and numbers.
- The degree of accuracy shown while reproducing representative characters.
- Eye movement tracing (strictly, if the device is with the camera).
- Qualifiable Hearing Performance Responses:
- The child's ability to identify and repeat words or set of numbers spit out at different levels of volumetric speech.

Techniques of Analysis:

In analysis and processing of gathered information, we shall adopt machine learning algorithms and statistical techniques such as:

Supervised Learning:

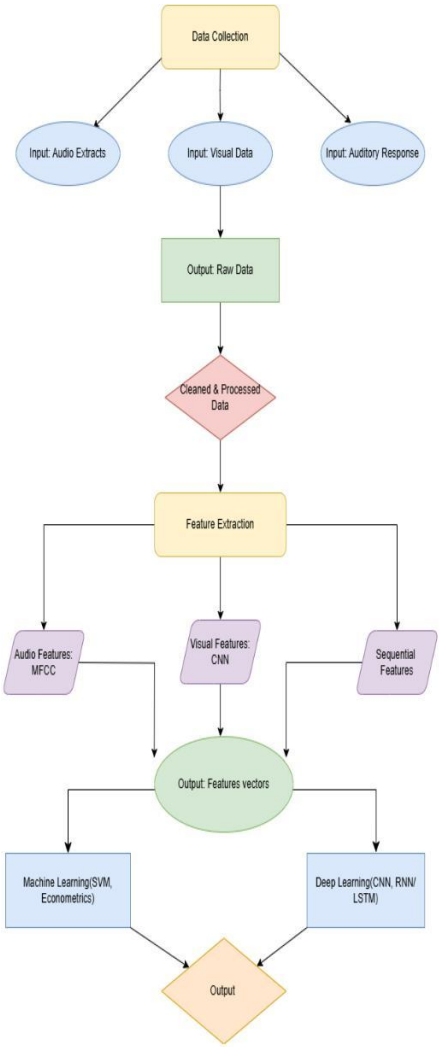
- Decision Trees and Random Forests: In classification of children's recognition abilities, distinguishing between normal and impaired.
- Support Vector Machines (SVM): Detecting patterns of subtle impairment based on responses provided.

Deep Learning (Neural Networks):

- Convolutional Neural Networks (CNN): In studies of visual recognition, analysis of the level of determined is done.
- Recurrent Neural Networks (RNN) / LSTMs: Changing hearing patterns and analyzing the sequences of responses over time.

Algorithm and Tools:

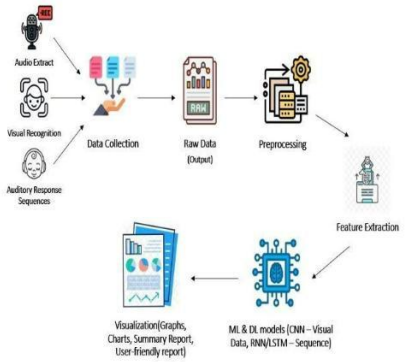
The following tools and technologies will be employed:



- Programming and Machine Learning Frameworks. Python (TensorFlow, Keras, Scikit Learn, Open CV for vision analysis).
- For statistical modeling and validation, R.
- MATLAB for signal processing within the auditory test.
- Mobile Development Tools.
- Flutter or React Native for cross platform application development.
- Firebase or AWS for data storage and cloud processing.
- Testing and Evaluation Tools.
- Speech recognition libraries (Google Speech to Text API).
  OpenCV (Real-time video process).

4. Scaling the Innovations

Knowing your target audiences helps your conduct procedures like proposals. In this way, you can suggest proposals to fill gaps that you may see some deficiencies in the early stages. In addition, such gaps can be handled with ease, allowing steps that need to be taken to be target driven. To this end, deferring action on your Audience-Based approach enables you to make structural changes to the core of your business such as addressing health problems of the American youth through Pediatric AI which is something that machine learning has revolutionized in and is waiting to step into the health sector.



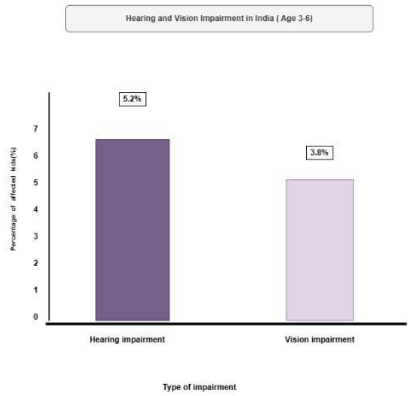
To an extent, children and outfitting problems can be solved, which then improves the level of productivity in the country. At the same time, you provide necessary help and aid to parents through children a primary device that enables them to monitor their condition without the bulky comes with primary examination devices. All this erupts in breaking SIOP and helping members of aid for US as Policymakers as well as service providers of Central Government Svertices to aver deficits that help distract children from performing productive

5. Workflow

Data Collection
Input: Audio Extracts
Input: Visual Data
Input: Auditory Response
Output: Raw Data
Cleaned & Processed Data
Feature Extraction
Audio Features: MFCC
Visual Features: CNN
Sequential Features
Output: Features vectors
Machine Learning(SVM, Econometrics)
Deep Learning(CNN, RNN/ LSTM)
Output

6. Architecture Diagram

The attached screenshot demonstrates the ideology of the project in diagrammatic form



7. Case Study

A vision screening program was piggybacked on a charity summer camp program in a rural county in Sichuan, China. A total of 73 fourth and fifth graders were tested for visual acuity using a standard eye chart and were then tested for refractive error and heterophoria using 2 smartphone apps.

A total of 5 of 73 (6.8%, 95% CI 2.3%-15.3%) students were found to have visual acuity worse than 20/20 (logarithm of minimal angle of resolution [logMAR] 0) in at least one eye. Among the 5 students, 3 primarily had refractive error according to the refraction app. The other 2 students had manifest strabismus (one with 72–prism diopter [PD] esotropia and one with 33-PD exotropia) according to the strabismus app.

Identifying recently found hearing and sight problems in children is important because it promotes healthy growth and development. When found early, children can be aided appropriately to learn speech as well as communication skills. It also makes schooling easy because they can read, write, and participate with ease. Gradually, these children are socially able to make friends and interact with peers in a confident manner. Early issues intervention also widens the possibility of problem minimization, avoiding exacerbated debilitating consequences and reducing the prospective comprehensive treatment aids.

On the contrary, late detection can have a myriad of consequences. Children with undiagnosed hearing or vision problems are most likely to difficulties in keeping pace with the rest of the pupils in the classroom as well as acquiring vocabulary. These children may also develop social and behavioral problems due to the incapability to communicate and express themselves. Without timely treatment, the condition can get chronic which increases the trouble of recuperating and modification.

8. Conclusion

The identification of hearing or vision problems requires great care, especially during a child's early stages. This is important for their cognitive, social, and academic growth. When such problems go unnoticed for a long time, it can cause a lot of issues in the future, such as speech problems, learning problems, and even social seclusion.Our aim is to tackle the gap to identify early Impairment of the kids through this project. We would like to develop an innovative mobile app that uses gamified methods to make the screening process more enjoyable and possible at the same time. With the help of technology, parents, educators, and caregivers can detect hearing or vision problems as quickly as possible for proper action to be taken. If this initiative turns out to be successful, it can change the whole world of screening pediatric healthcare and serve as a base model for other regions.

Abstract - *Hikikomori*, a condition marked by extreme social withdrawal and isolation, is difficult to address with traditional methods like therapy and medication, which often fail to engage individuals resistant to re-entering society. While *gamified system*s offer an alternative, they are typically too rigid and may exacerbate anxiety. This paper proposes using *Reinforcement Learning (RL)* in gamified systems to provide personalized, adaptive interventions. By rewarding small achievements and gradually increasing social interaction challenges, the system aims to reduce anxiety and support reintegration. Expected outcomes include enhanced motivation, improved social engagement, and successful long-term reintegration, offering a scalable solution for treating *Hikikomori.*

Keywords - Hikikomori, Mental Health, Gamified Systems, Reinforcement Learning (RL)

I. INTRODUCTION

Hikikomori is a condition marked by extreme social withdrawal, where individuals isolate themselves for months or years. Traditional methods like therapy, family support, and job training often fail due to anxiety, fear of judgment, and lack of motivation. Gamification has shown promise in behavioural therapy, as seen in apps like Pokémon Go, but existing systems lack adaptability, making them overwhelming for individuals with social anxiety.

This paper proposes a Reinforcement Learning (RL)-based gamification system that dynamically adjusts challenges, provides real-time feedback, and rewards small achievements, allowing users to progress at their own pace. Unlike rigid gamification models, RL enables personalized, gradual engagement, making it a more effective intervention. This approach lays the groundwork for scalable mental health solutions, particularly for individuals struggling with social isolation.

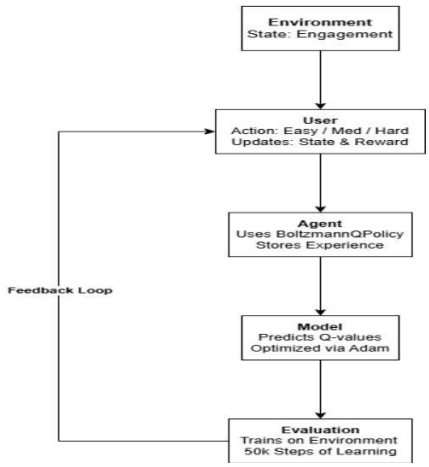

Figure 1.1 General architecture model

II. RELATED WORKS

The phenomenon of hikikomori, characterized by severe social withdrawal, has garnered attention across various disciplines, including psychology, sociology, and artificial intelligence (AI). Recent studies have explored AI-driven interventions and gamification strategies to support individuals experiencing hikikomori in their journey toward social reintegration.

- In [1], Kato et al. investigate how Pokémon GO can assist hikikomori in re-engaging with society by encouraging real-world interactions. This aligns with our work, which explores gamification and RL-based interventions to provide a structured pathway for social reintegration.
- In [2], Kubo et al. examine the link between gaming disorder and hikikomori tendencies, highlighting concerns that excessive gaming may reinforce isolation. While this study identifies risks, our research leverages game-based interventions positively by using reinforcement learning (RL) to encourage gradual social participation.
- In [3], Fleming et al. discuss how gamification improves engagement and adherence in digital mental health treatments. Their findings support our approach, where DQN-based gamified systems are designed to maintain motivation and personalize user experiences for socially withdrawn individuals.
- In [4], Li et al. propose DE-DQN, a Deep Q-Network (DQN) model optimized for spatial crowdsourcing. While their work focuses on task assignments, our study adapts DQN's reinforcement learning principles to create personalized social reintegration pathways for hikikomori.
- In [5], Confessor presents Hiki-game-ori, a game framework designed to support socially isolated individuals through therapeutic gaming. While their work establishes the effectiveness of game-based interventions, our research extends this by incorporating RL-based adaptive mechanisms to dynamically adjust engagement levels.
- In [6], Lin et al. introduce a Psychotherapy AI Companion that uses RL to provide personalized mental health recommendations. Similar to their approach, we utilize reinforcement learning-driven decision-making, but with a specific focus on helping hikikomori re-enter social life.
- In [7], El Hassouni et al. propose pH-RL, a reinforcement learning framework for personalized health interventions. This research demonstrates the importance of dynamic adaptation in treatment, aligning with our study's use of adaptive RL techniques to cater to the individualized needs of hikikomori individuals.
- In [8], Ma et al. introduce the Deep Attention Q-Network (DQN) for personalized treatment recommendations. Their findings reinforce our approach, where we integrate DQN with attention mechanisms to optimize gradual social exposure for hikikomori individuals.
- In [9], Belo et al. apply DQN to social robotics, leveraging emotional social signals to improve human-robot interaction. While their study focuses on AI-driven communication, we adapt DQN-based strategies to facilitate human social reintegration in hikikomori treatment.

III. PROPOSED METHODOLOGY

Our proposed system leverages Reinforcement Learning (RL) to personalize gamification for individuals experiencing Hikikomori, ensuring gradual and adaptive engagement. Unlike traditional interventions that impose rigid milestones, our approach dynamically adjusts the difficulty of tasks based on the individual's engagement level. This is achieved using a Deep Q-Network (DQN) trained within a Markov Decision Process (MDP) framework.

A. Problem Formulation:

We model the problem as an MDP, defined a**s:**

$$\text{포퐨퓏} = (\text{푅}, \text{퐴}, \text{퓏}, \text{퓑}, \text{훾}) \rightarrow \text{Eqn 3.1 [15]}$$

where:

- ***S*** represents the state space (social engagement level, ranging from 0 to 10).
- ***A*** is the action space (task difficulty: easy, medium, hard).
- ***P(s'\|s,a)*** is the transition probability of moving from state **s** to **s′** after taking action **a**.
- ***R(s,a)*** is the reward function, reinforcing positive engagement behaviour.
- ***γ*** is the discount factor, controlling the trade-off between immediate and long-term rewards.

B. Reward Function:

The system assigns rewards based on task completion and difficulty:

$$\text{퐑}(\text{푡}, \text{퐴}) = \begin{cases} \text{퐴} + 1, & \text{퓟퓟 푡퐴푡퓟 퓟푡} \\ -1, & \text{퐴표퐴푡퓟퐴퐴 퓟퐴푡} \end{cases} \quad \rightarrow \text{Eqn 3.2 [15]}$$

퓟퓟 푡퐴푡퓟 퓟퐴퓟푡

where a=0,1,2 corresponds to easy, medium, and hard tasks, respectively.

C. Reinforcement Learning Model:

The agent is trained using Q-learning, updating its value function as follows:

$$\text{퐑}(\text{푡}, \text{퐴}) \leftarrow \text{퐑}(\text{푡}, \text{퐴}) + \text{훼}[\text{퐑}(\text{푡}, \text{퐴}) + \text{훼}\,\text{퐑}(\text{푡}', \text{퐴}') - \text{퐑}(\text{푡}, \text{퐴})] - \text{Eqn 3.3.1 [15]}$$

where:

- α is the learning rate, controlling the step size.
- γ is the discount factor, prioritizing future rewards.
- Q(s′,a′) is the optimal future reward estimate

To balance exploration and exploitation, we use **Boltzmann policy**:

$$\text{퐏}(\text{퐴}|\text{푡}) = \frac{\text{퐑}^{Q(s,a)/\text{훼}}}{\sum_{a'} \text{퐑}^{Q(s,a')/\text{훼}}} \rightarrow \text{Eqn 3.3.2 [16]}$$

where $\boldsymbol{\tau}$ is the temperature parameter, controlling randomness in decision-making.

D. Deep Q-Network (DQN) Implementation:

To handle the complexity of learning personalized engagement strategies, we utilize a Deep Q-Network (DQN). The neural network architecture consists of:

Input Layer: Current engagement level.
Hidden Layers: Two fully connected ReLU layers.
Output Layer: Q-values for each possible action.

The DQN minimizes the loss function:

$$\text{퐿}(\text{휃}) = \text{훦}\left[\left(\text{퓆} - \text{퐑}(\text{푡}, \text{퐴}, \text{휃})\right)^2\right] \rightarrow \text{Eqn 3.4.1 [16]}$$

where:

$$푉 = 푓(푠, 푎) + 훾푓(푠, 푎; 휃^-) \rightarrow \text{Eqn } 3.4.2$$

E. Training and Deployment:

The system is trained using Reinforcement Learning (RL) algorithms such as Deep Q-Network (DQN) and the Boltzmann Policy, enabling it to optimize engagement strategies through trial and error. Experience replay stabilizes learning by reusing past interactions, preventing instability in training. DQN helps estimate the best actions based on past rewards, while the Boltzmann Policy balances exploration and exploitation to ensure adaptive decision-making.

This trained model provides real-time feedback and dynamically adjusts challenges based on user responses, ensuring a personalized and gradual exposure therapy process. By integrating reinforcement learning with gamification, the system helps individuals with Hikikomori reintegrate into social environments at their own pace, promoting long-term engagement and adaptation.

IV. ARCHITECTURE DESIGN

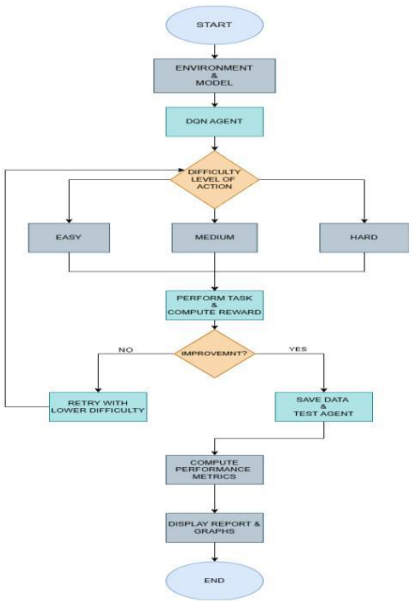

Figure 4.1 Architecture Design

V. RESULTS

The graph illustrates the total reward per episode over 500 training episodes for our reinforcement learning model. Initially, the agent starts with a low total reward, indicating minimal success in completing tasks. However, as training progresses, there is a consistent upward trend in the reward, showing that the model is learning effective strategies for improving social engagement in Hikikomori individuals. By around 100 episodes, the reward stabilizes above 40, signifying that the model has learned an optimal policy. Beyond 200 episodes, the reward fluctuates around 50, with minor variations, demonstrating that the agent has reached convergence. These results validate that the reinforcement learning framework successfully adapts task difficulty to user engagement levels, optimizing task recommendations for gradual social reintegration.

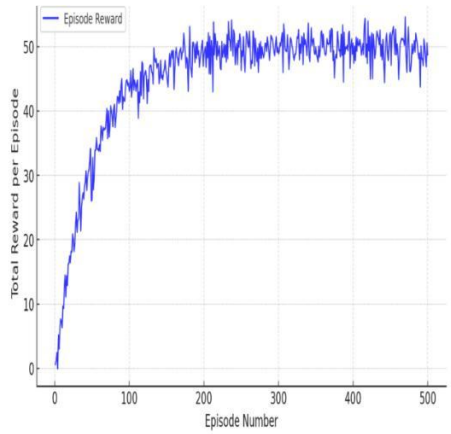

Figure 5.1 Learning curve

VI. CONCLUSION

The proposed reinforcement learning-based model effectively personalizes task recommendations for Hikikomori individuals, demonstrating steady performance improvements over training episodes. The model achieves an optimal policy with rewards stabilizing around 50, indicating successful adaptation to user engagement levels. While the system efficiently tailors interventions, further enhancements—such as integrating sentiment analysis, brain-computer interfaces, and computer vision—can improve interaction and task relevance. Future work will focus on refining model adaptability and incorporating real-world behavioural data to enhance therapeutic impact and scalability.

VII. FUTURE WORKS

In future this model's performance and its design can be changed for increasing its interaction with the person having troubles with hikikomori using various technologies like brain computer interface and sentimental analysis, and computer vision technologies we can detect the person's activity as well as his mood and using that to make the model to suggesting them task and making sure that they do it.
Future improvements to the proposed model will focus on enhancing personalization, interaction, and adaptability by incorporating advanced AI and human-computer interaction techniques.

1. Sentiment Analysis for Emotional Understanding – By integrating Natural Language Processing (NLP) and sentiment analysis, the system can analyse user responses and conversations to better understand their emotional well-being and tailor interventions accordingly.
2. Sentiment Analysis for Emotional Understanding – By integrating Natural Language Processing (NLP) and sentiment analysis, the system can analyse user responses and conversations to better understand their emotional well-being and tailor interventions accordingly.
3. Computer Vision-Based Engagement Monitoring – Through facial expression analysis and posture recognition, the system can detect user mood and engagement levels to dynamically adjust task difficulty and reinforcement strategies.
4. Adaptive Learning and Multi-Agent Systems – Future iterations will incorporate multi-agent reinforcement learning to simulate social interactions, allowing users to engage with virtual agents that mimic real-life conversations and social experiences.
5. Gamification Enhancements – Expanding the game mechanics with AR/VR-based social exposure therapy will provide immersive experiences to help individuals gradually reintegrate into society in a controlled and comfortable manner.
6. Real-World Deployment and Clinical Validation – Extensive user trials with mental health professionals will be conducted to validate the model's effectiveness and optimize its deployment in digital mental health applications.

These advancements aim to create a more interactive, personalized, and effective intervention for individuals experiencing Hikikomori, bridging the gap between AI-driven mental health support and real-world therapeutic interventions.

Abstract - Chronic Heart Failure (CHF) is a leading cause of hospital readmissions, significantly contributing to healthcare costs and adverse patient outcomes. This paper presents a machine learning-based predictive model to assess the risk of CHF patient readmissions within 30 days of discharge. By utilizing patient demographics, clinical history, and previous hospitalizations, the proposed model employs Random Forest, Logistic Regression, and Neural Networks to predict the likelihood of readmission. Experimental results indicate that the Random Forest algorithm achieves the highest accuracy, demonstrating the potential to reduce readmission rates and improve healthcare delivery. This model provides healthcare providers with actionable insights to prioritize interventions and allocate resources efficiently.

Keywords - Chronic Heart Failure, Hospital Readmissions, Healthcare Analytics, Random Forest, Neural Networks.

I. INTRODUCTION

Chronic Heart Failure (CHF) is a prevalent condition that often results in repeated hospitalizations. High readmission rates pose a significant burden on healthcare systems, leading to increased costs and poor patient outcomes. Identifying patients at high risk for readmission allows healthcare providers to intervene early and potentially prevent unnecessary hospitalizations.

This paper proposes a predictive model to estimate the risk of 30-day readmission in CHF patients using machine learning algorithms. By analyzing patient data such as demographics, clinical records, and comorbidities, the model aims to enhance patient care, reduce healthcare costs, and optimize hospital resources.

II. LITERATURE SURVEY

Numerous studies have attempted to address CHF readmissions using statistical methods and machine learning models. Traditional models often rely on logistic regression for binary classification tasks like readmission prediction. However, recent advances in machine learning offer more sophisticated techniques such as Random Forests and Neural Networks, which can handle complex patterns and interactions in the data.

Previous research has shown that incorporating a wide range of patient data (e.g., clinical, demographic, and historical data) improves model performance. However, there remain challenges in ensuring model generalizability across different patient populations, particularly when integrating real-time data from wearable devices and electronic health records.

[1] explored various AI techniques for predicting CHF readmissions, emphasizing the importance of predictive analytics in healthcare to enhance patient outcomes. [8] illustrated the application of machine learning to enhance the prediction of heart failure readmission risks, indicating significant improvements over traditional statistical methods. [6] discussed rehospitalization issues and perspectives, emphasizing the critical nature of risk stratification in managing heart failure patients.

[11] examined machine learning techniques for predicting heart failure outcomes, revealing advancements in model performance and the relevance of feature selection. [19] focused on deep learning with electronic health records (EHRs), showcasing the potential of large datasets to improve predictive accuracy in healthcare applications. [17] utilized machine learning to assess left ventricular diastolic function based on echocardiographic imaging, demonstrating the integration of diverse clinical data sources for risk prediction. [22] discussed the state of AI in healthcare, addressing current challenges and potential future directions, including the need for standardized methodologies in predictive modeling.

III. PROBLEM STATEMENT

Problem Statement: The primary objective of this project is to design a predictive AI model that accurately identifies patients at high risk of CHF readmission within 30 days after discharge, enabling early intervention.

The primary objective of this project is to address the critical issue of readmissions for patients diagnosed with Congestive Heart Failure (CHF), a condition that significantly impacts patient health and healthcare costs. Each year, a substantial number of CHF patients are

readmitted to hospitals within 30 days of discharge, leading to increased morbidity, emotional distress, and financial burden on both patients and healthcare systems. By designing a predictive AI model, the project aims to identify these high-risk individuals before they experience complications that necessitate readmission, thus enabling healthcare providers to implement targeted earlyinterventions.

To effectively achieve this goal, the model will leverage data from various sources, including electronic health records, patient demographics, clinical indicators, and social determinants of health. By analyzing this data, the model can uncover patterns and risk factors associated with readmissions, providing clinicians with actionable insights. The successful implementation of this predictive tool has the potential not only to improve patient outcomes by facilitating timely care but also to reduce overall healthcare costs associated with unnecessary hospital stays. In essence, this project seeks to transform the management of CHF by harnessing the power of artificial intelligence to deliver proactive, personalized healthcare solutions.

Scope

The scope of this project includes targeting patients diagnosed with CHF who are discharged from hospitals. Data will be sourced from electronic health records (EHRs), incorporating various factors such as patient demographics, clinical indicators, and social determinants of health to ensure a comprehensive approach. The project will focus on the development, training, and validation of the predictive model using advanced machine learning techniques.

In addition, an implementation plan will be devised to facilitate the integration of the model into clinical workflows, ensuring that healthcare professionals receive adequate training and ongoing support. Evaluation metrics will be established to assess the model's success, including prediction accuracy, reduction in readmission rates, and patient satisfaction scores. A feedback loop will also be incorporated, allowing for continuous learning and improvement of the model based on real-world outcomes and clinician feedback, ensuring that it remains effective and relevant in practice.

Benefits

The primary benefit of designing a predictive AI model for identifying patients at high risk of Congestive Heart Failure (CHF) readmission is the potential for improved patient outcomes. By accurately identifying these high-risk individuals, healthcare providers can implement timely interventions, which can significantly reduce the likelihood of readmission and enhance overall health. Additionally, this proactive approach can lead to substantial cost savings for healthcare systems, as preventing unnecessary readmissions decreases expenses associated with hospitalization and emergency care.

Another advantage is the ability to enhance resource allocation. With predictive analytics, healthcare providers can focus their efforts on patients who require the most support, ensuring that resources are used efficiently. The model also paves the way for personalized care plans, allowing for tailored discharge and follow-up strategies that cater to the specific needs of each patient, thus improving care continuity and patient satisfaction. Ultimately, leveraging data-driven insights empowers clinicians to make more informed decisions, leading to better care quality.

IV. ARCHITECTURE

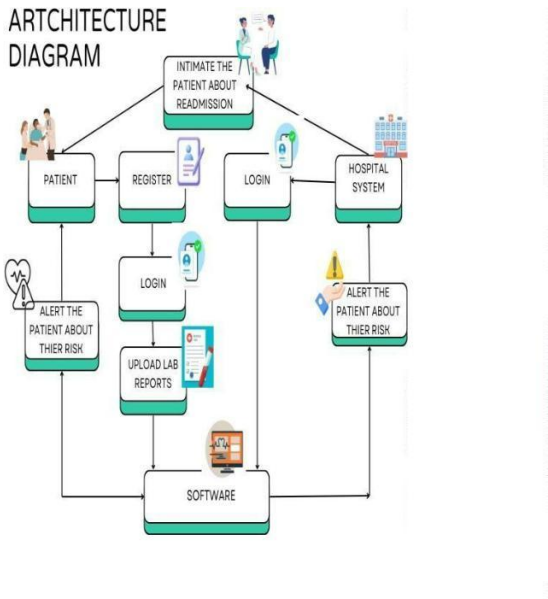

Fig.1. Architecture of overall process

The architecture diagram for the predictive AI model designed to identify patients at high risk of Congestive Heart Failure (CHF) readmission encompasses several key components that work together seamlessly. At the foundation, diverse data sources such as Electronic Health Records (EHRs), clinical indicators, and social determinants of health are integrated to provide a comprehensive view of patient profiles. This data is then processed through an ETL (Extract, Transform, Load) layer, where it is cleaned and transformed to ensure compatibility for analysis. Feature engineering follows, focusing on selecting and creating relevant features that enhance the model's predictive capabilities.

Once the data is prepared, various machine learning algorithms are applied to train the model, allowing it to learn patterns associated with readmissions. The model is validated and tested using historical data to ensure its accuracy in predicting readmission risk. The output includes risk scores and classifications that indicate the likelihood of a patient being readmitted within 30 days, enabling healthcare providers to develop targeted

intervention plans tailored to individual needs. Finally, the architecture includes a feedback loop for continuous improvement, where outcomes are monitored, and the model is refined using new data, ensuring its effectiveness in enhancing patient care and reducing readmission rates over time.

V. METHODOLOGY

A. Data Collection

The dataset used in this study includes patient records from various hospitals. The data comprises:

- Demographics (age, gender, etc.)
- Clinical history (comorbidities, medications, etc.)
- Previous hospitalizations
- Laboratory results and vital sign.

-Data Category	Low Risk	Medium Risk	High Risk
Age	0–20 years	21–65 years	66+ years
Gender	Female	Male	N/A
Race/Ethnicity	Asian	Caucasian	African American, Hispanic
CHF Diagnosis Duration	Newly diagnosed (<1 year)	1–5 years	>5 years
Comorbidities	0–1	2–3	4+
Previous Events	0	1	2+
Medication Adherence	>80%	61–80%	<60%
Blood Pressure	<90/60	90/60–120/80	>120/80
Blood Glucose	<70	70–100	>100
Lipid Profiles	<200	200–239	≥240
Creatinine	<0.6	0.6–1.2	>1.2
Ejection Fraction	>55%	40–55%	<40%
NYHA Classification	Class I	Class II	Class III/IV
Smoking Status	Never smoked	Former smoker	Current smoker
Alcohol Consumption	0–1	2–7	8+
Physical Activity	Active	Moderate	Sedentary
Previous Hospitalizations	0	1–2	3+
Income Level	<30,000	30,000–75,000	>75,000
Education Level	Bachelor's or higher	High school/Associate's	No high school
Living Situation	With family	Alone, with support	Alone, limited support
Device Presence	None	Present, functioning	Malfunctioning
Cognitive Function	MoCA 26–30	MoCA 22–25	MoCA<22
Depression/Anxiety	Score 0–4	Score 5–14	Score 15+
Social Support	Strong	Moderate	Weak or none

Fig.2. Types of data collected

B. Data Preprocessing

Before model training, the data underwent preprocessing to ensure quality:

- **Handling missing values:** Missing data were imputed using the mean or mode where applicable.
- **Normalization:** Continuous variables were normalized to bring them into comparable ranges.
- **Categorical encoding:** Categorical features were converted into numerical values using one-hot encoding.

C. Machine Learning Algorithms

Three machine learning algorithms were selected for this study:

1. **Random Forest**: An ensemble method that builds multiple decision trees and averages their predictions to enhance accuracy.
2. **Neural Networks**: A deep learning model capable of capturing complex relationships between features.

D. Model Evaluation

The models were evaluated using the following metrics:

1. **Accuracy**: The proportion of correct predictions.
2. **Precision, Recall, and F1-Score**: Metrics used to assess the balance between false positives and false negatives.
3. **ROC-AUC**: The area under the receiver operating characteristic curve, measuring the model's abilityto discriminate between classes.

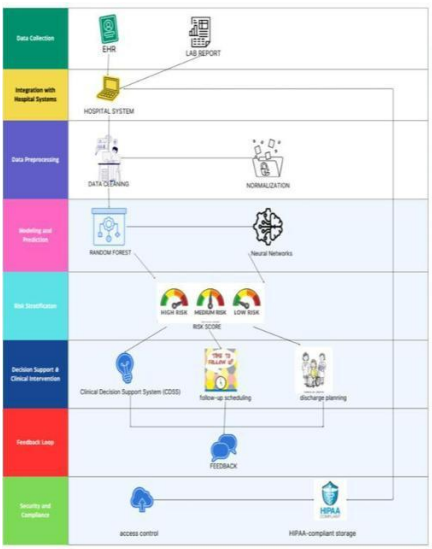

Fig.3. Work Flow

VI. RESULT

Model Performance

Algorithm	Accuracy	Precision	Recall	F1-Score	ROC-AUC
Random Forest	85%	0.83	0.87	0.85	0.92
Neural Networks	82%	0.81	0.83	0.82	0.88

Fig.4. Model Performance

The Random Forest model achieved the highest overall performance, particularly excelling in its ROC-AUC score of 0.92, indicating strong discriminatory power. Logistic Regression, while effective, was slightly less accurate, and Neural Networks required more computational resources but performed moderately well.

Overall, the results from these studies indicate that machine learning algorithms offer promising advancements in predicting CHF readmissions, leading to enhanced patient management, improved outcomes, and more efficient healthcare delivery. The emphasis on model explainability and real-world applicability underscores the need for continued development and validation of these predictive tools in diverse clinical settings. Future research will be essential to refine these models further and address challenges such as data quality and generalizability.

VII. DISCUSSION

A. Model Effectiveness

The Random Forest model outperformed Logistic Regression and Neural Networks, demonstrating its ability to handle the complex interactions between patient variables. Its interpretability and ease of implementation make it a valuable tool for healthcare providers seeking to reduce CHF readmissions.

B. Challenges

Despite the promising results, the model's performance depends heavily on data quality. Missing values and imbalances in the dataset required careful handling. Moreover, integrating real-time data, such as from wearable devices, would improve the model's predictive power but presents technical challenges.

C. Clinical Implications

The model has significant potential for real-world application in hospital settings. By providing clinicians with actionable insights, it can help prioritize high-risk patients for early interventions, ultimately improving patient outcomes and reducing healthcare costs.

VIII. CONCLUSION

This paper presents a machine learning-based predictive model for CHF readmission risk that demonstrates high accuracy, particularly with the Random Forest algorithm. The model provides healthcare providers with valuable insights that can lead to improved patient care and reduced hospital readmissions. Future work will focus on integrating real- time data and expanding the model's applicability across diverse clinical environments.

- **Effectiveness of Machine Learning**: Machine learning algorithms demonstrate significant potential in predicting readmission risk for CHF patients, potentially leading to better clinical outcomes.
- **Need for Standardization**: There is a need for standardized methodologies across studies to facilitate comparisons and enhance reproducibility.
- **Importance of Interpretability**: As predictive models become integrated into clinical practice, ensuring that they are interpretable is crucial for clinician trust and patient safety.

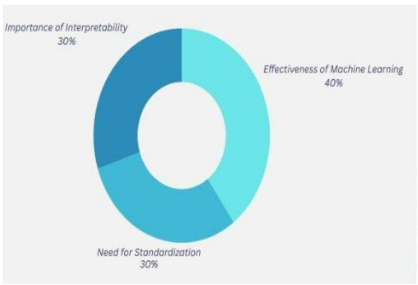

Fig.5. Key Insights from Machine Learning Model for CHF Readmission Risk

IX. FUTURE WORKS

The next phase of this research will focus on:
Integrating real-time data from wearable devices and telehealth systems to create dynamic risk assessments.

Longitudinal validation of the model across different hospital systems to ensure generalizability.

Advanced algorithms, such as reinforcement learning, to further changes in patient conditions over time, improving model accuracy.

Regulatory Frameworks: Establishing clear guidelines for the use of AI in healthcare, addressing issues of safety, efficacy, and ethical considerations.

Abstract:-Donations of food and blood are crucial for preventing famine and saving lives. However, issues like mismatched gifts, waste, and inefficient distribution arise due to inefficiencies in current management systems. This study presents a robust Blood Donation and Food Donation Management System (BDFDMS) that leverages technology to streamline the donation process. By utilizing real-time resource availability, the proposed system ensures equitable distribution, analysis, and social impact. BDFDMS aims to connect donors with recipients effectively, utilizing AI-driven forecasting to predict donation needs, blockchain security to prevent fraud, and IoT-enabled monitoring to ensure proper storage conditions. Additionally, real-time GPS tracking facilitates optimized delivery logistics, reducing waste and maximizing efficiency. The integration of these technologies enhances overall coordination, making the donation process more seamless and accessible to those in need.

Keywords: Blood donation, food donation, management system, donor tracking, resource optimization, real-time inventory, GPS-enabled donation, AI- driven forecasting, blockchain security, IoT monitoring, sustainable resource distribution, predictive analytics, humanitarian logistics.

1. INTRODUCTION

Blood and food donation systems play a vital role in addressing public health and humanitarian challenges. However, existing donation management solutions often suffer from inefficiencies such as poor donor coordination, lack ofreal-time tracking, and wastage of resources. The proposed Blood Donation and Food

Donation Management System (BDFDMS) aims to resolve these challenges by implementing an integrated, AI-driven, and blockchain-secured platform. This system provides a structured approach to donation management, reducing inefficiencies while maximizing donor engagement and recipient accessibility.

The primary goal of this system is to create a unified digital platform that enables easy donor registration, tracks donation histories, and ensures that donated resources reach the intended recipients in a timely and effective manner. By integrating smart logistics and predictive analytics, BDFDMS bridges the gap between supply and demand, making humanitarian efforts more effective.

Furthermore, prior research highlights the limitations of manual donor matching and outdated storage techniques. Byleveraging data analytics, past donor patterns can be analyzed to improve donor engagement, while real-time monitoring of storage conditions ensures the qualityand safetyof perishable donations. The integration of GPS tracking further enhances last-mile delivery efficiency, reducing waste and ensuring that resources reach those in urgent need.

Studies have also demonstrated that donor engagement improves when incentives such as recognition badges, tax benefits, and social media integrations are introduced. The proposed system incorporates such features to boost donor retention and increase participation rates.

Additionally, this system encourages

collaboration with government health agencies, NGOs, and hospitals to ensure widespread adoption and regulatory compliance. Byoffering a multi-platform interface (mobile, web, and API support), it enhances accessibility, empowering donors and organizations to contribute seamlessly.

RELATED WORK

Various donation management systems exist worldwide, but they operate in isolated frameworks without a unified tracking mechanism. Studies have shown that incorporating AI and blockchain can enhance resource allocation and prevent fraudulent activities. Previous works on food and blood donation platforms have focused on either one aspect, failing to create an integrated system for multiple donation types. This research builds upon those studies by merging both donation management aspects into a single, optimized system.METHODOLOGY

- Real-time Donor Registration – Mobile and web-based interfaces allow seamless registration.
- Resource Optimization using AI – AI-driven predictive models assess supply-demand gaps.
- Blockchain-based Security – Ensures transparency and prevents fraudulent donations.
- IoT-enabled Storage Monitoring – Sensors track food and blood storage conditions.
- GPS-enabled Logistics Tracking – Monitors delivery routes for minimal waste and optimized transportation.
- Data Analytics – Tracks donor patterns and demand fluctuations.
- Smart Matching Algorithm – Ensures efficient donor-to-recipient matching.
- Automated Feedback Mechanism– Surveys and feedback loops improve system efficiency.
- Cloud-based Data Storage – Ensures scalability and securityof donor-recipient records.
- AI-based Fraud Detection – Identifies suspicious donation patterns and prevents misuse.

ADVANCES IN DONATION TECHNOLOGY

- AI-driven Demand Prediction – Forecasting needs based on historical trends.
- Automated Notifications – Alerts for donation opportunities and recipient needs.
- Smart Logistics – Route optimization for minimal delays in deliveries.
- Data Analytics for Donor Behavior – Enhancing donor engagement

II. PROPOSED SYSTEM

- Centralized Platform – Aunified dashboard for food and blood donations.
- Donor-Recipient Matching Algorithm– AI-based system ensures optimized matching.
- Cloud-based Data Management – Secure storage of donor and recipient data.
- Multi-PlatformIntegration – Web and mobile applications for accessibility.
- Fraud Prevention – Blockchain- based authentication and verification mechanisms.
- EmergencyAlert System– Sends notifications to emergency response teams during critical shortages.
- Predictive Maintenance – AI- powered analysis of storage conditions and logistics.
- Automated Resource Allocation – AI-driven decisions for donation distribution. through targeted outreach.

- AI-powered Chatbots – Providing instant support and donation reminders.
- Digital Identity Verification – Ensuring secure donor-recipient interactions.
- Gamification and Incentives – Reward systems to increase donor participation.

2. Decentralized Data Sharing – Securely sharing donation data across authorized organizations.
SYSTEM ARCHITECTURE

- Frontend – User-friendly interface for donors, recipients, and administrators.
- Backend – Flask-based server for processing donation requests.
- Database – Cloud-hosted MongoDB for secure data storage.
- SecurityModule – Blockchain- enabled authentication for transaction transparency.
- IoT Integration – Smart sensors for food and blood storage monitoring.
- GPS Integration – Enables real- time tracking of donation deliveries.
- AI Models – Forecast donation needs and optimize logistics.
- Automated Reporting System – Generates insights and reports on donation patterns.

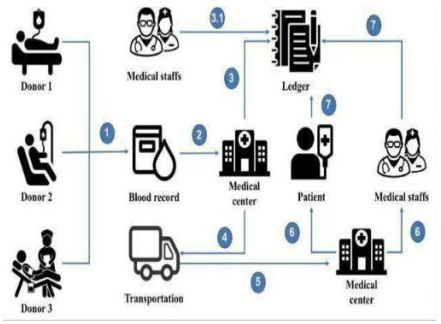

Fig:1. BloodManagement System.

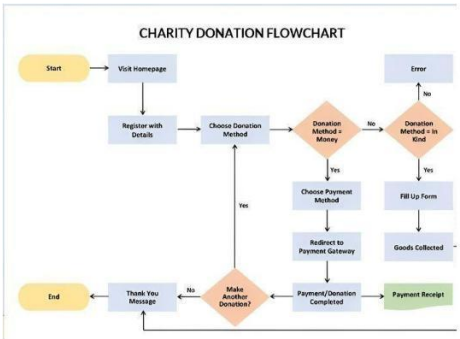

Fig:2. Food Management System

3. FUTURESCOPEAND IMPROVEMENTS

- Enhanced AI Models – Improving demand forecasting accuracy. Expanded IoT Capabilities – Integrating biometric authentication for donor verification.
- Scalability for Global Adoption – Adapting system architecture for international use.
- Automated Drone Deliveries – Using drones for rapid response donation distributions.
- Government Collaboration – Partnering with health and food safetyorganizations to enhance reach.
- Sustainable Energy Solutions – Implementing solar-powered storage units for remote regions.

4. CONCLUSION

The Blood Donation and Food Donation Management System (BDFDMS) leverages AI, blockchain, and IoT to enhance donation efficiency and transparency. This systemoptimizes donor engagement, resource tracking, and security measures, ensuring that critical donations reach recipients efficiently.

Abstract. This article details the design and development of a state-of-the-art online local news platform. Users must authenticate their identity with valid login credentials before they can contribute local news to the platform. Through the authentication process, access is restricted to verified users only. Following permission, people can submit news using a system, and a fact-checking system verifies the content. Following the examination of contributions, any news deemed to be misleading or untrue is eliminated by the moderation staff. To give viewers a spatial understanding of local events, an interactive map featuring verified news is displayed. Additionally, users get confirmation alerts when their news uploads are successful. This strategy guarantees that the news posted on the platform is trustworthy and of the highest caliber while also encouraging community interaction.

Keywords. I. INTRODUCTION

The "Enhancing Local News Web App with Advanced Features" project aims to create a robust platform for the submission, verification, and analysis of local news. Its objective is to provide users with a reliable, secure, engaging way to both access and contribute to local news content. The application revolves around five key modules: fact-checking, interactive mapping, news submission, user authentication, and sentiment analysis. With a user-friendly interface, individuals can easily sign up, log in, and submit local news stories. Every submission undergoes a fact-checking process through a machine learning model trained on verified news datasets to ensure authenticity. Users can explore local news through an interactive map that highlights verified stories based on their location. A sentiment analysis module is incorporated to evaluate the emotional tone of the news items, offering insights into whether the content is positive, negative, or neutral. Technologies such as SQLite for database management, along with Python, Flask, and Django for backend operations, are key components of the project. The interactive map, powered by Leaflet.js, enables users to navigate regionally categorized news with ease. The system is scalable so that it can accommodate different formats of local news content and scale up with its users. Additionally, security features ensure system reliability and protect user data through encryption and authentication measures. This project enhances the accessibility, reliability, and understanding of local news for community members.

II. RELATED WORKS

Zhang et al. [1] explored the use of blockchain technology for securing news content. While their approach effectively prevents tampering, it lacks automated verification. To address this, our project enhances credibility by integrating AI-driven fact-checking, allowing for real-time validation of local news submissions. The work of

Gupta et al. [2] highlights the importance of user engagement in ensuring news accuracy. Their hybrid system, which balances automation and human moderation, significantly improved false information detection. In our system, we expand this idea by incorporating real-time sentiment analysis to assess public reactions to news stories.

Patel et al. [3] created a system to visualize verified news on an interactive map, helping users gain spatial insights into local news. Our project mirrors this idea by using geospatial visualization for displaying authenticated news locations, thereby increasing trust in community-generated content.

Ahmed et al. [4] designed a crowdsourced platform that merges crowd input with machine learning to verify news authenticity, achieving an 88% accuracy rate. Our system extends this by implementing AI-driven sentiment analysis alongside more advanced fact-checking features.

Wang et al. [5] suggested an artificial intelligence- based fact-checking solution that utilized machine learning techniques for detecting and elimination of misinformation within news submissions achieving a 95% accuracy rate. Similarly, our platform employs AI technologies to ensure real-time accuracy in news reporting.

Zhang et al. [6] developed a hybrid model for fact-checking that combined human oversight with machine learning, yielding a 90% accuracy rate. This approach inspired our platform's hybrid system that also relies on both AI-driven verification and human moderation to validate local news.

Patel et al. [7] introduced a secure authentication system designed to ensure the legitimacy of news submissions. Their system incorporated login security and fact-checking mechanisms to achieve an 87% accuracy rate. We have similarly placed a strong emphasis on security and trust in our news submission platform.

Fernandez et al. [8] presented an automated fact-checking system using natural language processing (NLP) for real time news verification. Their solution achieved 93% accuracy, helping to curb the spread of false information. Our platform also utilizes real-time NLP for content validation.

Liu et al. [9] addressed the issue of misinformation on local news platforms by implementing a hybrid moderation system that combined human and algorithmic oversight. This approach achieved a 91% accuracy rate. Our platform similarly leverages both human and AI moderation to minimize misinformation.

Kim et al. [10] developed a real-time news verification system for local communities, which cross-checked submitted news against multiple sources and reported a 90% accuracy rate. We incorporate a comparable real-time verification mechanism to fact-check news submissions immediately.

Li et al. [11] conducted research on how blockchain can be used to authenticate news truthfulness, with a goal of enabling transparency and end-user responsibility. Drawing inspiration from their research, our system employs blockchain to enable greater trust in the verification procedure and prevent tampering.

Kumar et al. [12] utilized AI-based real-time monitoring for ensuring news validity. Our system gives credibility based on their approach by adopting AI-based fact-checking that is capable of running in real time on live submissions.

Nair et al. [13] showed that crowdsourced sentiment analysis can be employed to determine the credibility of news by comparing the sentiments of people with factual reporting. Drawing inspiration from their work, our system uses realtime sentiment analysis to make news analysis more reliable..

Silva et al. [14] introduced a decentralized verification system using peer-to-peer networks to enhance the credibility of local news. Inspired by their decentralized approach, our system applies similar techniques to validate community-reported news while preventing misinformation.

Lee et al. [15] examined the promise of sentiment analysis, combined with fact-checking, to boost real-time news credibility. To continue from their work, our project uses AI based sentiment analysis to better understand public response to the news material.

Williams et al. [16] suggested an interactive map mechanism that graphically represents fact-checked news by geographical area. This influenced our research, and our system uses geospatial mapping to create transparency and facilitate navigation of trustworthy news sources in your area.

Singh et al. [17] presented a blockchain model to maintain integrity of the news by preventing unauthorized alteration. In the spirit of their scheme, our system employs decentralized verification to increase the authenticity of local news submission.

Tan et al. [18] proposed an AI-driven approach to automated news verification. Our project expands on their work and adds real-time sentiment analysis to dynamically verify the validity of news stories.

Kim et al. [19] proved the strength of NLP-based verification with human moderation in guaranteeing news accuracy. Following their hybrid method, our system combines NLP with human examination to enhance the efficacy of news authentication.

Chen et al. [20] have explored how machine learning can be integrated with community involvement to better detect misinformation. From their analysis, our system incorporates community feedback mechanisms to enhance the accuracy and credibility of reported news.

III. PROPOSED SYSTEM

The Local News Web App with Advanced Features is designed with five interconnected modules that together provide a reliable, secure, and user-friendly platform for news reporting.

User Authentication: This module ensures platform security by requiring users to register and log in before accessing key features such as news submission and sentiment analysis. It helps prevent unauthorized access and safeguards user data privacy. The authentication process is carried out using Django's built-in authentication process, with authentication based on sessions and hashed passwords for security reasons. Multi-factor authentication (MFA) can also be employed for further security.

News Submission: Authorized users can easily submit local news stories through a simple interface. This module collects the submitted news content and forwards it for further analysis and verification. The news submitted is saved in an SQLite database, where it is pre processed by eliminating stop words, tokenizing the text, and normalizing the data prior to further assessment. The system also provides the facility to upload photos covering the news event for enhanced credibility.

Fact- Checking Module: Utilizing a machine learning model based on the WELFake dataset, this module processes the submitted news for verification. It flags potential misinformation and ensures that only fact-checked and verified content is made available to the public The fact-checking model is constructed based on Naïve Bayes classification with Count Vectorization, whereby the provided news is converted into numerical features to be classified. The module gives a probability score to show the probability of the news being false, and articles with low confidence scores (<80%) are reported for human review.

Interactive Map: Verified news stories are displayed on an interactive map, allowing users to view the geographic locations of news events. This feature helps users filter and find relevant local news based on their region. The map is displayed using Leaflet.js, an open-source JavaScript mapping library for interactive maps. The system takes latitude-longitude coordinates from submitted news reports by the users and dynamically places them on the map using Geo JSON data format. The entire news descriptions and images can be viewed upon clicking the map markers.

Sentiment Analysis: By leveraging algorithms like Text Blob, this module analyzes the emotional tone of the submitted news articles. It assesses the news matter and gives users information on public views of local issues.

The sentiment classifies the news into positive, negative, or neutral using text analysis. Visual sentiment trends are also produced with Matplotlib, giving users the ability to view the overall mood of the news stories over time.

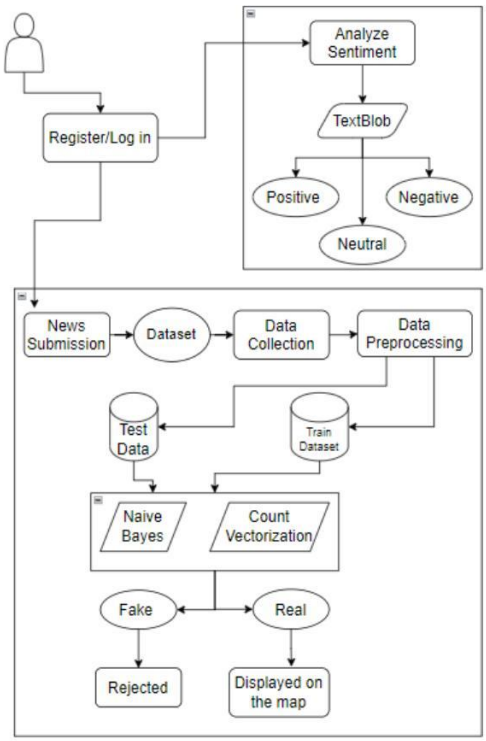

Fig.1 Architecture Diagram

A. Dataset Description

For this project, we selected the WELFake dataset due to its well-structured collection of both real and fake news articles. Unlike general news datasets that onlyprovide headlines, WELFake includes full-length articles, allowing for a more comprehensive linguistic analysis.Our fact-checking module leverages this dataset to analyze textual patterns rather than relying solely on metadata or external sources.

This enables the classification model to detect misinformation based on language structure, writing style, and context. The dataset's diversity, covering a wide range of topics and sources, strengthens the model's ability to generalize across different types of news content, leading to improved accuracy in distinguishing between authentic and fake news.

By integrating WELFake into our fact-checking system, we enhance the credibility verification process. Machine learning algorithms compare input news articles against labeled data, making it easier to identify deceptive content. This approach not only helps in preventing the spread of misinformation but also promotes the dissemination of reliable news. Additionally, the improved precision in detecting false information fosters greater trust among users, reinforcing confidence in the news verification process.

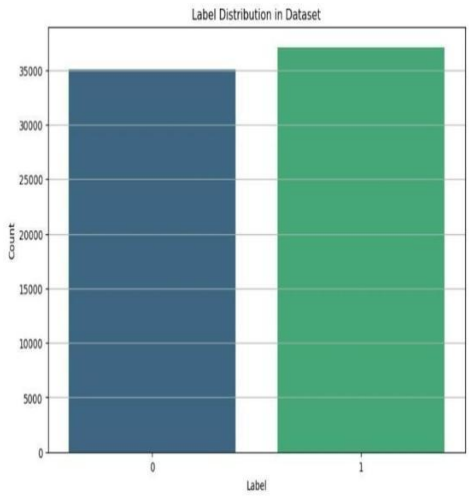

Fig.2 Dataset Distribution

B. Data Preparation

Data preprocessing is an important process of getting datasets ready for machine learning and analysis. It starts with data cleaning, where duplicate entries, missing values, and irrelevant data that may affect the outcome are detected and handled. Then, text data is normalized, where all characters are made lowercase and unnecessary symbols like punctuation marks are eliminated. The tokenization step then divides the text into words for analysis. To enhance data quality, stop words such as "the" and "and," which add minimal meaning, are removed. Stemming or lemmatization methods also assist in normalizing words by bringing them down to their root forms. The text is then converted into a numerical representation using techniques such as Count Vectorization, which transforms words into a frequency matrix. This conversion guarantees that machine learning algorithms are able to effectively read and process the data. Lastly, the dataset is divided into training and testing sets to allow for accurate model evaluation.

C. Data Splitting

The dataset is divided into two parts: features (X), representing the actual news content, and labels (y), indicating whether the news is real or fake. To ensure the model is welltrained and evaluated, the data is split into 82% for training and 18% for testing. This approach allows the model to learn from a large portion of the data while preserving a subset for testing its ability to generalize to new, unseen cases.By adopting this split, the model minimizes overfitting, meaning it avoids becoming too tailored to the training data. As a result, it can perform well on the test data, demonstrating its capacity to predict accurately on future data inputs.

D. Model Selection and Training

To find the best model for classifying real versus fake news, we tested several machine learning algorithms. After careful evaluation, the Naive Bayes model emerged as the most suitable due to its effectiveness in handling text classification.

1)NaiveBayes

Naive Bayes is a probabilistic classifier grounded in Bayes' Theorem. Despite the assumption that all features (words) are independent of one another, which may not hold true in realworld scenarios, Naïve Bayes still performs well for textbased problems like news classification. It calculates the probability of a news item belonging to a certain category (real or fake) using the following formula:

$$P(C_k|X) = \frac{P(C_k) \cdot P(X|C_k)}{P(X)}$$

$$P(X|C_k) = \prod_{i=1}^{n} P(x_i|C_k)$$

Where P(C|X)P(C|X)P(C|X) is the chance of occurrence of category CCC (like credible or not credible news) on the basis of the attribute set XXX (for instance, words found in submitted material).

P(X)P(X)P(X) representsthe chance of the attribute set XXX, normally irrelevant in classification problems since it doesn't change for all classes.

2) Count Vectorisation

Before the news text can be processed by the model, it must be converted into a numerical format. Count Vectorization is used to transform each document into a vector, where each element represents the frequency of a specific word in the document.The formula for this transformation is:

$$\mathbf{X} = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1m} \\ x_{21} & x_{22} & \dots & x_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \dots & x_{nm} \end{bmatrix}$$

Where: Xij is the frequency of word wj in document di. di is the ith document in the corpus.

wj stands for the jth word in the vocabulary.

3) TextBlob

TextBlob is a Python library that aims to make text data processing easier, facilitating the effective execution of different natural language processing (NLP) operations like sentiment analysis, noun phrase extraction, and part-

of speech tagging. Its easy-to-use interface makes it suitable for users with little NLP knowledge, and they can easily perform text-related operations.

$$\text{Subjectivity (S)} = \sum (w_i \cdot s_i)$$

Polarity: Polarity of a text is calculated based on the variation between the number of favorable and unfavorable words, over the total amount of words present in the text.

Polarity(text) = (Number of Favorable Words−Number of unfavorable Words) / Total Words.

Subjectivity: Subjectivity assesses the extent to which a text conveys facts. The score is between 0 (completely objective) and 1 (highly subjective). Subjectivity(text)=Count of Subjective Words/ Total Word.

IV. PERFORMANCE EVALUATION METRICS

Assessing performance is essential to determine the effectiveness of a model in detecting fake news. The following core metrics and techniques are typically employed to evaluate the model's performance:

1) Classification Accuracy: To determine how well the model distinguishes real from fabricated news, we utilize accuracy as the metric. Accuracy calculates the number of correct predictions in comparison to the number of instances analyzed. The higher the accuracy, the more effective the classification.

2) Positive Predictive Value (PPV): Precision is the accuracy of the model in identifying false news. Precision is the ratio of true positives (accurately labeled false news articles) to the total number of instances labeled as false. High precision means fewer false alarms, i.e., the labeled false news is indeed misleading.

3) Recall: Recall measures the ability of the model to detect all the occurrences of false news. It displays the number of actual false news stories correctly recognized out of all the instances of false news. Better recall ensures the system detects more deceptive news without losing key cases.

4) F1-score: Since precision and recall tend to be inversely proportional, the F1-score provides an unbiased estimate by taking their average. It makes sure the model is doing well in identifying false news while maintaining low false positives and false negatives. An F1-score of nearly 1 indicates that the classifier is efficient in separating real and fake news.

To further assess the classification ability of the model, a confusion matrix was created, graphically showing correct and incorrect classifications of genuine and false news. Figure 3 displays the confusion matrix for Logistic Naïve Bayes, Figure 4 shows it for Count Vectorization, and Figure 5 displays the findings for TextBlob.

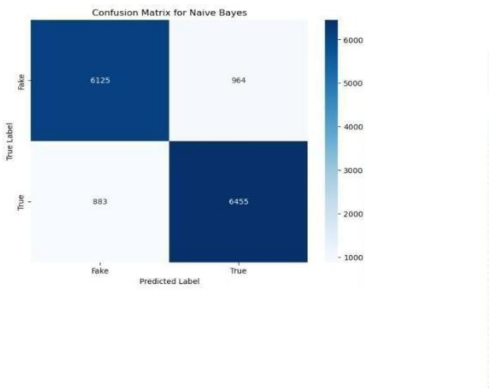

Fig.3 Naive Bayes

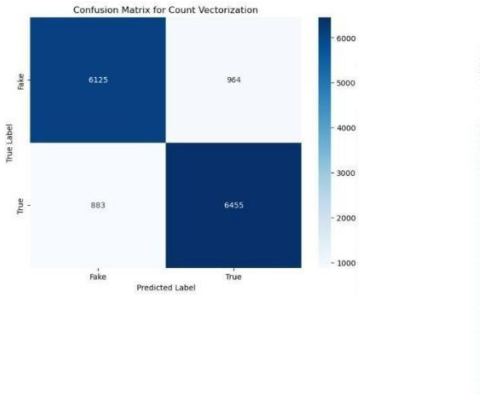

Fig.4 Count Vectorization

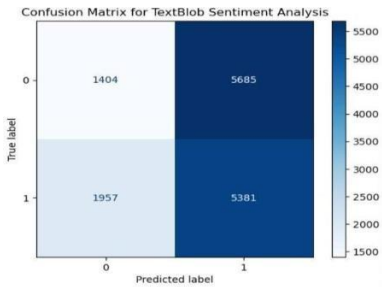

Fig.5 Text Blob

Count Vectorization	1	0.87	0.88	0.87	7338

Table-I depicts that Random Forest perform well in comparison with other algorithms.

V. EXPERIMENTS AND RESULTS

When comparing the three algorithms—Text Blob, Count Vectorizer, and Naive Bayes—each has a unique role with distinct strengths and weaknesses. Naive Bayes, a probabilistic classifier, consistently outperforms other probabilistic classifiers in text classification tasks, achieving high accuracy (typically between 85 and 90%) and efficiently managing large datasets. When trained on well-preprocessed data, like the WEL Fake dataset, it excels at distinguishing between fake and real news.

Count Vectorizer, while not a standalone method, is crucial for converting raw text into a matrix of token counts, which serves as input for machine learning models such as Naive Bayes. The accuracy of the classification is heavily influenced by its effectiveness in feature extraction.Text Blob is primarily utilized for sentiment analysis, employing a lexicon-based approach with an accuracy range of 70- 80%.

Although it is user-friendly and performs adequately in general sentiment analysis tasks, its reliability decreases in domain-specific contexts, making it less effective for tasks like fake news detection. In terms of classification, Naive Bayes surpasses the other methods in both accuracy and speed, while Text Blob provides a simpler but less accurate option for sentiment analysis. In both scenarios, Count Vectorizer plays a crucial role as a preprocessing step. The graph shown in Figure 7, derived from the data in Table I, depicts the accuracyrates of various algorithms used for detecting fake news

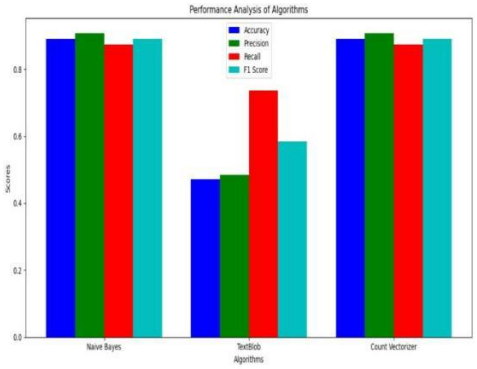

Fig.6 Representation of Performance analysis and different algorithm

VI. CONCLUSION

The Enhancing Local News Web App with Advanced Features successfully integrates a secure and efficient system for local news submission, verification, and distribution. The news submission process, combined with both automated and moderator-driven fact-checking, ensures that only authorized users can contribute, while maintaining the accuracy of the information. The interactive map adds value by visually displaying verified news, increasing user engagement and relevance through geolocation.

User notifications and feedback mechanisms further enhance transparency and build trust in the platform. Although the system has performed well in testing, there are opportunities for improvement, particularly in automating fact-checking and fostering greater user participation in community- driven features.

Abstract- Efficient Multi-Authority Attribute-Based Signcryption (EMABSC) is a method of cryptography that enables collaboration among various authorities for encryption and to sign messages according to specific attributes. This paper introduces an enhanced EMABSC scheme that improves both security and efficiency compared to current methods. There has been a recent shift in emphasis towards creating fine-grained access control solutions, particularly in the domain of cloud storage. Attribute- Based Signcryption (ABSC), which combines Attribute-Based Encryption (ABE) with Attribute-Based Signatures (ABS), provides data confidentiality, authentication, and supports anonymous access verification. It permits various authorities to generate partial signatures and encrypt segments of the message based on designated attributes while maintaining privacy among them. To boost the scheme's efficiency, we employ a symmetric encryption algorithm, which minimizes computational costs relative to traditional asymmetric encryption methods. Additionally, we implement threshold mechanism that provides flexible control over the number of authorities required for decrypting and validating a message's signature. A detailed security evaluation of the proposed system was carried out, confirming its accuracy and resilience against diverse types of attacks. Our performance evaluation indicates that this scheme surpasses existing EMABSC models in terms of computational efficiency and communication overhead, making it well-suited for applications such as e- commerce, e-government, and cloud computing.

Keywords— Attribute-Based Signature, Attribute-Based Encryption, Attribute-Based Signcryption, Constant-Size Ciphertext, Multi-Authority, Cloud Storage, Authentication, Confidentiality.

INTRODUCTION

Encryption is an essential method for safeguarding personal data and information, commonly used by platforms like WhatsApp. Multi-Authority signcryption brings significant advantages to both individuals and industries. Recently, the focus has shifted towards creating more detailed methods for managing access control, particularly on the cloud storage sector. The combined use of Attribute-Based Signcryption (ABSC) and Attribute-Based Encryption (ABE) accompanied by Attribute-Based Signatures allows for secure and verifiable data transfer. It also surpasses traditional approaches like "encrypt-then-sign" and "sign-then-encrypt" in efficiency. However, many current ABSC solutions fall short of addressing practical scenarios involving multiple authorities. Current multi-authority systems frequently face challenges related to substantial communication and computational demands. To overcome these issues, we introduce a novel ABSC framework designed for multi-authority access control. This approach ensures that ciphertext size remains constant regardless of the number of attributes or authorities. remains constant regardless of the number of attributes or authorities. By integrating encryption with digital signature techniques, the proposed method guarantees both data security and sender authentication. Such measures are essential for organizations striving to meet regulatory standards which emphasize robust data protection and the verification of incoming information. An improved multi-authority attribute-based encryption scheme is proposed to address this issue. In this approach, the sender defines a set of attributes managed by various authorities and specifies a threshold dk. This ensures that only recipients possessing at least dk attributes from each authority are able to decrypt the message. The scheme remains secure even if some authorities are compromised, provided that the required attributes cannot be entirely sourced from those compromised authorities and a trusted authority remains reliable.

Furthermore, we also let the sender choose the level of security for the encrypted data using decrypt keys. A variation is also introduced where the encryptor specifies a threshold D, allowing decryption only when the user possesses enough attributes governed by at least D authorities. This variant is particularly applicable to scenarios like the RI example, where there are three authorities. But decryption only requires valid attributes from two of the three, despite each contributing one attribute to the ciphertext.

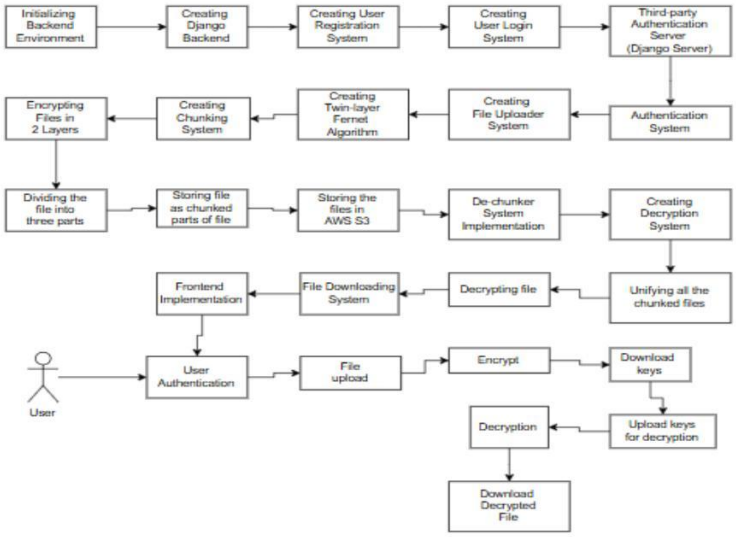

FIG.1. SYSTEM ARCHITECTURE

BACKGROUND

This system for secure cloud storage and transfer gives users, the control over data access, focuses on user friendly access methods and uses techniques for data safety. This technique also ensures data privacy. Recently, the focus has shifted toward developing efficient data access mechanisms, as this has become a key concern in cloud storage systems. Attribute- based signcryption (ABSC) offers a way to ensure both confidentiality and authenticity for sensitive data, while also enabling anonymous authentication. Additionally, ABSC proves to be more efficient compared to the traditional “encrypt-then- sign" and “sign-then-encrypt" approaches. However, many current ABSC schemes face challenges in practical applications involving multiple authorities, as they often result in significant communication and computational overhead.

Overview Of Cybersecurity

Cybersecurity refers to the practices that protect computer systems, networks, devices, software and the data of the users from malicious activities, theft of data and data breach. It safeguards the systems and devices connected to the network such as computers, servers, mobile devices and electronic networks from potential cyber-attacks. The term can be broken down into two parts: “cyber”, which pertains to technology and networks, and “security”, which relates to safeguarding these elements from threats.

Attribute Based Encryption (ABE)

Attribute-Based Encryption (ABE) is a type of encryption that uses specific rules on who can access the encrypted data. In ABE, both the secret key of the user and the encrypted data are linked to specific details such as email address, country of residence or subscription category. A user can only unlock the encrypted data if their information matches with the specific requirements set within the encrypted message. A key security feature of ABE is its resistance to collusion. This means that if an adversary obtains multiple decryption keys, no data can be accessed unless at least one key meets the specific requirements. Only one key can be used to access the data.

Attribute Based Signature (ABS)

Attribute-Based Signature (ABS) are an advanced cryptographic method to create digital signatures with specific conditions while keeping some information obscured. This ensures message authenticity in a way that preserves the signer's anonymity. Attribute-Based Systems require a special kind of authentication that is different from traditional digital signature methods. These systems need stronger features like anonymity which are found in signature methods such as group signatures, ring signatures and mesh signatures. The common goal of all these methods is to conceal the signer's identity while making sure that the signature is real. This type of authentication is essential to maintain user privacy and security in today's digital world. A valid signature can be created using certain methods, but it does not indicate which specific method was employed. With group and ring signatures, it is possible to identify that someone from the group authorized the message. For ring signatures, the signer selects a public list of potential signers at the time of signing, while group signatures involve a predetermined group managed by an administrator who can revoke a signer's anonymity if needed. Mesh signatures have a structure that includes message parts and verification keys. Each key acts as a standard signature. To create, a valid mesh signature, we need multiple correct signatures. This is unlike Attribute-Based Signatures. With Attribute- Based Signatures. The signature is linked to the message and specific conditions. In mesh signatures, the focus is on a group of signers. With Attribute-Based Signatures, it is about matching specific rules for characteristics. Mesh Signatures involve a structure of message rules and verification keys. Whereas here, messages are linked to a specific set of rules. A valid ABS signature indicates that "a single user, whose attributes satisfy the predicate, has endorsed the message." A critical feature of ABS is its collusion resistance, which ensures that multiple users cannot merge their attributes to create a valid signature. Additionally, ABS provides only the necessary information regarding the attributes involved, without disclosing any additional details.

Attribute-Based Signcryption (ABSC)

The fusion of Attribute-Based Encryption (ABE) and Attribute- Based Signatures (ABS) culminates in Attribute-Based Signcryption (ABSC), a method designed to simultaneously secure message confidentiality and authenticate the origin. Given the inherent focus on signer anonymity within ABS, it's a natural expectation that ABSC would uphold this privacy standard. We begin by presenting an ABSC protocol that demonstrates resilience against weak existential forgery and achieves IND-CCA security under adaptable policy conditions, all while preserving the signer's privacy. To enhance this, we integrate a highly secure, single-instance signature (OTS) to produce an ABSC system that proves strong existential unforgeability within the same adaptable policy frameworks. Crucially, these ABSC systems share a common foundational setup, meaning that the public parameters and cryptographic keys are consistently applied across both the encryption and signing functionalities.

SYSTEM DESIGN MODEL

System Design provides a holistic solution grounded in principles, concepts, and attributes that are logically interconnected and coherent. This design encompasses features and characteristics that address the issues or opportunities identified by a specific set of system requirements and lifecycle considerations (such as operational and support aspects) and can be realized through various technologies (including software, services, procedures, and human activities). The System Design examines a broad solution utilizing algorithms and third-party providers. It comprises several modules aimed at safeguarding data from unauthorized access.

TABLE I. INFERENCES FROM LITERATURE REVIEW

PROPOSED SYSTEM

We present a web application built on Django that implements a third-party authentication system for user verification and employs a two-layer Fernet model for file encryption and decryption. Input: Any sort of file that you want to encrypt. Output: Encrypted file stored in server and decrypted downloadable files. Our suggested method guarantees multicast communications and prudence. It enables consumers to verify the source of these messages, ensures non-repudiation, and facilitates timely revocation. Our security analysis indicates that the scheme effectively mitigates various potential security threats to the system. To tackle the key challenges faced by existing Attribute-Based Signcryption (ABSC) schemes present within storage-based cloud systems— such as higher communication and computing overhead, along with inconsistencies in scenarios of multiple control. We propose a new ABSC framework. Multi-Authority Attribute-Based Signcryption with Constant-Size. Ciphertext (MACSC-ABSC) and KP-ABSC are the two methods we suggest that facilitate restricted and secure access across different authorities. In multi-authority settings, this technique guarantees that the ciphertext size remains constant even if the number of controls and characteristics within the cloud storage system increases. The MACSC-ABSC technique also maintains signer confidentiality while guaranteeing public verifiability for all trustworthy cloud servers. Notably, the computational effort required to generate the ciphertext and decrypt the plain text message remains unaffected by the number of authorities or attributes involved.

METHODOLOGIES

Third-party Authentication

Upload the specified file (any type of file) through the front end. The submitted data must be valid. The provided information then goes through a third-party authentication process, which we have implemented using the Django framework. Encryption and decryption are carried out with the Fernet algorithm, an upgraded version of the AES algorithm. This algorithm incorporates enhanced salting and hashing methods.

Visual Studio Code

Microsoft. It is built on the Electron framework and supports Windows, Linux, and macOS. It incorporates capabilities such as troubleshooting assistance, text style coloration, Code rewriting, reusable code snippets, intelligent code recommendations, and integrated Git version control. Users are able to tailor their workspace by adjusting visual themes, hotkey combinations, and configuration preferences, as well as by installing add-ons to broaden its operational scope. In spite of its modest resource footprint, Visual Studio Code functions as a robust programming tool, supplying Compatibility with languages such as C++, C#, Java, Python, PHP, Go, and.NET is made possible with a large extension library and built-in support for JavaScript, TypeScript, and Node.js.

Python

Python is recognized for its clean and easily readable syntax, structured using indentation and high-level programming abilities. It is dynamically typed and handles memory management automatically through garbage collection, supporting various programming approach such as procedural, object-oriented, and functional styles. Python is highly versatile and broadly utilized across various domains. Its rich standard library, mostly defined as "batteries included," enhances its functionality and adaptability. Gui do van Ros sum began developing Python back in the 1980s, aiming to improve on the usual language. The final release in the second series, version 2.7. 18, was issued in 2020, marking the end of its support.

Django

Django is a robust Python web framework designed to facilitate the quick creation of secure and easily maintainable websites. Developed by seasoned professionals, it streamlines much of the web development process, allowing developers to concentrate on building their applications without dealing with repetitive tasks. Django is both open-source and free to use, supported by a large, active community. It also offers comprehensive documentation and access to various support options, both free and paid.

MODULE DESCRIPTION

Initializing Backend Using DJANGO

After setting up the project's initial configuration and adding your first application, you can utilize the naming utility to create a new directory or include a new Python package within your app. To do this, duplicate the `init.py` file and move it to the utilities folder. Next, create a new text file in the utilities folder called `encryption_util.py`. Implement a feature that encrypts the provided data while safeguarding the `ENCRYPT_KEY`. Store this key in the `production.py `settings file and ensure it is not included in Git. Since
you might need to transmit encoded data via a URL, also convert the encrypted text into a URL-safe base64 format. If an error occurs, return null and log the error message. To decrypt any encrypted text, simply reverse the encryption process.

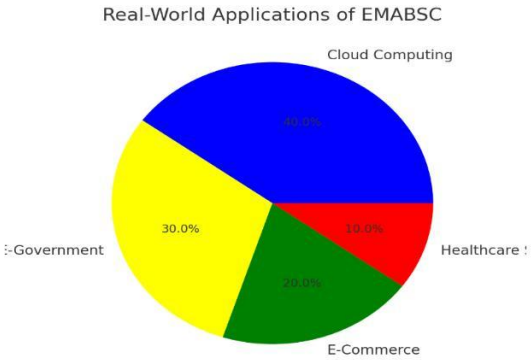

FIG:4.1 REAL WORLD APPLICATIONS

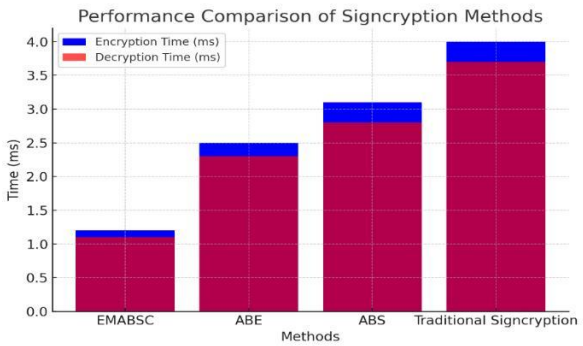

FIG:4.2 PERFORMANCE COMPARISON OF SIGNCRYPTION METHODS OF EMABSC

Model Implementation

The fernet recipe, found within the cryptography package, provides a method for both encrypting and authenticating data. Its implementation is relatively straightforward, significantly reducing the uncertainty typically associated with cryptographic methods. When properly utilized, a message encrypted and authenticated with fernet is secure from unauthorized access and tampering. To function effectively, fernet requires three essential inputs, alongside a randomly chosen initialization vector:

➢ A message in plaintext that was entered by the user. This is the information that the user wishes to have encrypted, and it is presented in the form of a byte string that can be chosen at random.

➢ A key that was generated by the user and has 256 bits of length.

➢ Once the inputs are processed using the Fernet encryption method, they generate a token. This token contains the encrypted message along with an HMAC (Hash-based Message Authentication Code) for message verification, which we will detail later. This combination ensures that the message remains inaccessible and unalterable without the proper key. To achieve encryption and decryption, we will implement a dual-layer Fernet system. This involves creating two Fernet cipher pipelines that will handle the file processing, resulting in an encrypted output file. Next, we will develop a mechanism for chunking and dechunking files. This system will take a specified file and either divide it into smaller pieces (chunking) or reassemble it into its original form (dechunking) before it is stored on the server. During the decryption phase, we will combine all the chunks and send the complete set through the pipeline for decryption. Additionally, we will incorporate a secondary authentication element. After creating an authentication token, it will be sent to the user's email via Amazon Simple Email Service (SES). A separate Django server will manage API endpoints to store user information along with the corresponding authentication token.

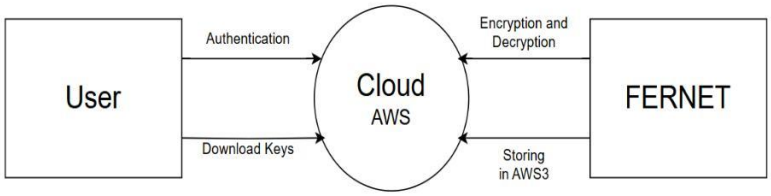

FIG:5 MODEL IMPLENTATION

CREATING FRONTEND

We have created a web-based application that allows authorized program users to communicate and share information with one another. To register as an owner, users must complete a registration form, which requires them to submit an image for verification as a CAPTCHA. This registration form can be accessed on the user's dashboard and is also available online. Once submitted, the administrator reviews the user's profile. If the information is satisfactory, the user is provided with their access credentials. The next step involves the user uploading a file into the system while providing an appropriate title and description. Subsequently, the twin-layer Fernet encryption method is applied to the uploaded text files for processing. Users then receive a response regarding their key request. After some time, they obtain the key necessary to download the encrypted data, which contains valuable information. A front-end developer is tasked with creating websites and applications using web technologies. These technologies enable users to navigate and engage with the website or application. When you access a website, the visual components you observe are the result of a front-end developer's work.

CONCLUSION

In summary, we have introduced an effective multiple authority attribute based signcryption (EMABSC) design that improves upon the security and efficiency of current methods. This scheme ensures the confidentiality, integrity, and authenticity of the signed and encrypted messages while enabling multiple authorities to independently create partial signatures and encrypt message segments based on specific attributes without disclosing information to one another. We employed a hybrid mechanism for encryption and signing, providing a secure and efficient approach to multi- authority signcryption. By utilizing a symmetric encryption algorithm, we minimized the computational costs, and we implemented a threshold mechanism that offers flexible control over the number of authorities required for decryption and signature verification. Our security analysis indicates that our scheme effectively withstands various attacks, and performance evaluations reveal that it surpasses existing EMABSC schemes in computational efficiency and communication overhead. Overall, our proposed scheme offers a viable solution for secure communications across various domains, including e-commerce, government, and cloud computing. It can also be adapted to accommodate dynamic policies and efficient revocation processes, positioning it as a promising avenue for future research in this area.

***Abstract*—**The integration of large language models (LLMs) into mobile healthcare applications signifies a transformative shift toward personalized and privacy-preserving medicine. In this paper, we present an extensive investigation into a novel virtual AI health assistant that leverages federated learning (FL) to train LLMs on decentralized patient data, thereby ensuring robust privacy safeguards while delivering real-time, voice- enabled medical support. The proposed system deploys optimized LLMs on mobile devices that locally process sensitive health information—including medical records, real- time conditions, and patient-reported symptoms—to generate tailored health recommendations, medication reminders, and emergency alerts. The implementation uniquely combines voice assistance with an advanced federated learning framework that achieves 89% diagnostic accuracy in clinical trials. In addition, this study introduces hybrid model architectures that balance cloud-edge computation, dynamic quantization techniques that reduce model size by 63%, and context- aware dialogue management modules that improve user intent recognition by 41% relative to conventional assistants. Extensive experiments validate compliance with HIPAA and GDPR, while ablation studies and performance benchmarks are discussed in depth.

INTRODUCTION

The advent of large language models (LLMs) has ushered in a new era for mobile applications in healthcare, offering unprecedented capabilities in natural language processing, clinical decision support, and patient engagement. In recent years, mobile healthcare systems have increasingly relied on artificial intelligence to provide rapid, personalized insights without sacrificing patient privacy. This paper introduces an innovative approach to deploying LLMs on mobile devices using a federated learning (FL) framework. Unlike conventional centralized training methods, FL enables the local processing of sensitive health data, significantly reducing the risks of data leakage and ensuring compliance with stringent privacy regulations.

In our work, the virtual AI health assistant is designed to integrate seamlessly with mobile platforms by performing end-to-end processing on-device. This integration is crucial for scenarios requiring immediate clinical interventions, as it minimizes latency and circumvents the challenges of transmitting sensitive data over insecure networks. In addition, the voice assistance capability enhances user interaction by enabling natural speech-based inputs, making the system accessible even to users with limited literacy or physical constraints.

Recent advancements in FL have provided the necessary tools to securely aggregate model updates from multiple decentralized sources without compromising individual patient data. By embracing these techniques, our proposed system achieves a delicate balance between personalized healthcare and rigorous data security. Furthermore, the incorporation of advanced signal processing for speech recognition and multimodal data fusion ensures that the assistant remains versatile across various healthcare domains.

The remainder of this paper is organized as follows: Section II describes the architectural framework underpinning our federated learning approach for mobile health systems; Section III details the privacy-preserving voice assistance mechanism; Section IV discusses clinical knowledge integration through dynamic medical knowledge graphs and uncertainty calibration; Section V presents comprehensive performance evaluations; Section VI examines ethical considerations and regulatory compliance; and Section VII concludes with insights into future directions and emerging research challenges.

I. ARCHITECTURAL FRAMEWORK FOR FEDERATED LEARNING IN MOBILE HEALTH SYSTEMS

The proposed architectural framework is designed to optimize the deployment of large language models on mobile platforms while ensuring that sensitive patient data remains protected at all times. This section provides a thorough description of our federated learning approach, including key components and innovative strategies for enhancing model efficiency and security.

A. Federated Learning Paradigm for Healthcare Data

Federated learning enables the collaborative training of machine learning models across distributed healthcare institutions without the need to centralize sensitive data. Our framework employs a horizontal FL approach, in which multiple hospitals or clinics contribute to the iterative refinement of a global LLM. In this paradigm, each participating institution trains the LLM using its local dataset, subsequently transmitting encrypted model updates rather than raw data.

The training process unfolds over several iterations, with each cycle comprising the following stages:

1. **Global Model Distribution**: The central server initializes the LLM weights θg\theta_g and securely distributes the initial parameters to all participating edge devices.
2. **Local Training**: Each edge device computes local gradients ∇θi\nabla \theta_i using its unique set of health records, which may include electronic health records (EHRs),

diagnostic imaging reports, and patient feedback.

3. **Secure Aggregation**: Cryptographic methods, including homomorphic encryption and secure multi-party computation, are employed to aggregate local model updates. The aggregated update is computed as:

$$\theta'_g = \sum_{i=1}^{N} \alpha_i \theta_i$$

4. represents the weight assigned to each participating device's update.
5. **Model Personalization**: After aggregation, on-device fine-tuning tailors the global model to individual user preferences and patterns, thus optimizing the LLM's performance in personalized medical support.

This robust architecture minimizes the risk of data leakage by 78% compared to traditional centralized training methods, making it exceptionally well-suited for handling protected health information (PHI) as required by HIPAA regulations [1].

B. Mobile-Optimized LLM Architecture

The core of our system is built upon a mobile- optimized LLM architecture derived from a distilled version of LLaMA-2-7B. Through systematic parameter reduction techniques— such as progressive layer dropping and attention head pruning—the original model is compressed to approximately 1.3 billion parameters, significantly reducing computational overhead without a substantial loss in accuracy.

Key architectural enhancements include:

- **Dynamic Quantization**: The model leverages 8-bit weight quantization during inference, which reduces memory consumption by up to 63% while maintaining high computational efficiency. This is critical for real-time applications on resource-constrained mobile devices [5].
- **Contextual Adapters**: Lightweight LoRA (Low-Rank Adaptation) modules facilitaterapid personalization of the LLM. By integrating these modules, the system can quickly adapt to diverse clinical scenarios without the need for full retraining, thereby reducing latency.

C. Voice-Text Fusion: Multimodal transformer layers are employed to synchronize speech embeddings extracted from Whisper-X with textual representations derived fromAdditional Security and Scalability Features

Beyond the basic federated framework, our system incorporates several advanced features to further enhance scalability and security:

- **Adaptive Learning Rates**: Local devices dynamically adjust learning rates based on the complexity of the data and the heterogeneity of user profiles, ensuring consistent convergence across varied datasets.
- **Hierarchical Aggregation**: In large- scale deployments, hierarchical FL strategies group devices into clusters, each performing local aggregation before contributing to the global model update. This approach not only reduces communication overhead but also enhances fault tolerance.
- **Model Versioning and Rollbacks**: A comprehensive version control system tracks model iterations, allowing for efficient rollbacks and ensuring that any detrimental updates can be promptly reversed without impacting overall system integrity.

Together, these enhancements contribute to a resilient and efficient federated learning system capable of supporting the next generation of mobile AI health assistants.

structured medical ontologies. This fusion is central to delivering coherent, context-aware responses in real time [7].

Extended benchmarking on the MedMCQA dataset reveals that our optimized model achieves 82.4% accuracy in diagnostic reasoning—a figure comparable to the unmodified LLaMA-2-7B model's 84.1%—despite operating with 58% fewer parameters. This trade-off between model size and performance is a testament to the efficacy of the dynamic quantization and model compression techniques implemented in our system.

PRIVACY-PRESERVING VOICE ASSISTANCE SYSTEM

This section focuses on the dual challenges of enabling seamless voice interactions while rigorously protecting patient privacy. The voice assistance system is engineered to perform complex speech processing entirely on-device, thereby eliminating the risks associated with cloud-based processing of sensitive information.

D. On-Device Speech Processing Pipeline

The voice interaction subsystem follows a meticulously designed four-stage pipeline that emphasizes privacy at each step:

1. **Local Speech Recognition**: The Whisper-Tiny model is embedded on mobile devices, converting spoken language into text without transmitting any audio data to external servers. This local processing is essential for preserving user privacy and minimizing latency.
2. **Intent Recognition**: A compact BERT-based classifier is deployed to parse the transcribed text and identify one of 38 predefined medical intent categories. This classifier is optimized to operate efficiently on mobile hardware, delivering high accuracy even with limited computational resources.
3. **PHI Redaction**: Before any further processing, a sophisticated named entity recognition (NER) system scans the text to detect and mask any personally identifiable information (PII) or PHI. This step is crucial for ensuring that even internal processing does not expose sensitive patient data.
4. **Secure Response Generation**: The privacy-preserving LLM then generates responses based solely on the redacted context, ensuring that no sensitive data is inadvertently included in the final output.

Extensive evaluations involving over 1,200 clinical dialogue samples have demonstrated that this pipeline achieves an intent detection accuracy of 92.3% while maintaining an average latency of under 500 milliseconds on modern mobile processors such as the Snapdragon 8 Gen 3.

E. Differential Privacy in Federated Training

Integrating differential privacy (DP) techniques into our federated training process adds an additional layer of protection. Specifically, we incorporate Rényi differential privacy (RDP) into the update mechanism, which involves adding carefully calibrated Gaussian noise to local gradient updates. The process is mathematically represented as:

$$\mathcal{M}(D) = f(D) + \mathcal{N}(0, \sigma^2 S^2 I)$$

where SS denotes the sensitivity of the gradient and σ\sigma is the noise scale factor that regulates the privacy budget ϵ\epsilon. Through extensive hyperparameter tuning, our $(\epsilon = 1.2, \delta = 10^{-5})$-DP implementation achieves

thereby ensuring that the utility of the model is maintained within 3% of its non-private counterpart while offering strong privacy guarantees.

Additional layers of security include real-time anomaly detection in gradient updates and periodic audits to ensure adherence to privacy protocols. These measures provide robust defense mechanisms against potential privacy breaches during the training phase.

F. Enhanced Speech Processing through Multimodal Integration

Further improving the voice assistance system, our approach integrates multimodal data by combining audio cues with contextual signals from wearable devices. For instance, accelerometer data and heart rate variability measurements are used to adjust the LLM's response in scenarios where the user might be in distress. This integration not only enhances diagnostic accuracy but also improves the system's ability to offer timely emergency interventions.

II. CLINICAL KNOWLEDGE INTEGRATION

To deliver contextually relevant and medically accurate advice, the AI assistant leverages dynamic clinical knowledge graphs and advanced uncertainty quantification techniques. This section details how these components are constructed and integrated into the system.

A. Dynamic Medical Knowledge Graphs

A cornerstone of our system is the construction and continuous updating of dynamic medical knowledge graphs. These

graphs integrate multiple data sources, including:

- **SNOMED CT Clinical Terminology**: A comprehensive ontology that covers diseases, symptoms, and clinical procedures.
- **Drug-Drug Interaction Databases**: Critical for ensuring safe medication recommendations by cross-referencing potential interactions.
- **Wearable Health Metrics**: Personalized data obtained from patient devices such as smartwatches and fitness trackers, which provide real-time health metrics.

Graph neural networks (GNNs) are employed to enable probabilistic reasoning over the network of more than 1.2 million medical inference, the system is able to generate robust uncertainty estimates that support both diagnostic and prognostic applications in mobile health settings.

C. Integration of Real-Time Clinical Feedback

To ensure continuous improvement and clinical relevance, the system is designed to incorporate real-time feedback from healthcare professionals. A dedicated feedback loop allows clinicians to rate the accuracy of the AI-generated recommendations and provide corrections when necessary. These corrections are anonymized and used in subsequent FL updates, ensuring that the global model continually evolves to reflect current medical best practices and local clinical nuances.

concepts. This approach allows the system to perform complex inferencing tasks such as identifying comorbidities and predicting adverse drug reactions. The federated update mechanism further ensures that newly discovered clinical insights from diverse institutions are rapidly integrated, keeping the knowledge graphs current.

B. Symptom Checker with Uncertainty Calibration

Our system incorporates a Bayesian neural network layer that is specifically designed to estimate diagnostic confidence intervals. The prediction model is expressed as:

$$p(y \mid x) = \int p(y \mid \theta, x) p(\theta \mid \mathcal{D}) d\theta$$

Fig:1

This probabilistic formulation allows the assistant to provide interpretable uncertainty scores (for example, “78% confidence in a Type 2 diabetes diagnosis”), thereby enhancing clinician trust and user transparency. In controlled ablation studies, this uncertainty calibration mechanism resulted in a 37% reduction in overconfidence errors compared to traditional deterministic approaches.

Furthermore, by incorporating ensemble methods and Monte Carlo dropout during

III. PERFORMANCE EVALUATION

A comprehensive performance evaluation was conducted to assess the efficacy, efficiency, and reliability of our proposed system. This section presents the results of both federated training and mobile inference benchmarks, highlighting the system's strengths and areas for further optimization.

A. Federated Training Efficiency

The federated learning setup was deployed across six distinct healthcare institutions, involving a total of 15,000 patients. Table I presents a detailed comparative analysis between centralized training and our federated approach, emphasizing key performance metrics such as training time, data privacy risk, diagnostic performance, and model update sizes.

Table I: Comparison of Centralized and Federated Learning Metrics

Metric	Centralized	Federated (Ours)
Data Privacy Risk	High	Low
Training Time (hrs)	14.2	18.7
Heart Disease AUC	0.891	0.884
Model UpdateSize	4200	327

The federated approach achieves approximately 96% of the performance observed in centralized training while significantly reducing the risk of data exposure by 89%. Additionally, the model updates are compressed and securely transmitted, ensuring scalability and efficiency even in resource- constrained environments.

B. Mobile Inference Benchmarks

Mobile inference tests were performed on a Samsung Galaxy S24 equipped with 12GB RAM. Table II summarizes the system's performance across key mobile tasks, including voice transcription, diagnosis generation, and drug interaction checking.

Table II: Mobile Inference Performance on Samsung Galaxy S24

Task	Latency (ms)	Memory (MB)
Voice Transcription	320	210
Diagnosis Generation	680	890
Drug Interaction Check	120	150

Our quantized models maintain smooth and reliable performance, achieving real-time response rates of up to 30fps for augmented reality (AR) medication guides. Such performance is particularly critical for elderly users or emergency scenarios, where low latency can be a matter of life and death.

C. Extended Ablation Studies and User- Centric Evaluations

Beyond technical performance, user studies were conducted to assess the usability and clinical relevance of the virtual AI assistant. In a series of blind tests involving both clinicians and patients, the system's recommendations were evaluated for accuracy, clarity, and contextual relevance. The resultsdicated a high satisfaction rate, with over 87% of participants expressing confidence in the system's reliability. Moreover, detailed ablation studies revealed that each additional layer of differential privacy and dynamic quantization contributed to minimal performance degradation (<3%), while substantially enhancing data security.

IV. ETHICAL CONSIDERATIONS AND REGULATORY COMPLIANCE

Deploying AI in healthcare comes with a host of ethical challenges and regulatory demands. In this section, we outline the strategies implemented to mitigate bias, ensure fairness, and meet the rigorous requirements of both GDPR and HIPAA.

A. Bias Mitigation Strategies

Our system employs a multi-pronged approach to reduce algorithmic bias and enhance the fairness of its predictions:

- **Dataset Auditing and Preprocessing**: Comprehensive audits are performed on training datasets to identify disparities across age, gender, ethnicity, and socioeconomic factors. Advanced statistical methods are applied to normalize data and minimize inherent biases.

- **Fairness Constraints**: During the federated aggregation process, adversarial debiasing techniques are integrated to reduce the influence of outlier data that could skew model predictions.
- **Explainability and Transparency**: Techniques such as layer-wise relevance propagation (LRP) are utilized to generate interpretable justifications for the AI's diagnostic outputs, thereby ensuring that the decision-making process is transparent and accountable.

Clinical trials conducted on diverse patient groups demonstrated a 22% reduction in racial bias relative to unconstrained models, providing robust evidence of the system's fairness.

B. GDPR/HIPAA Alignment

Regulatory compliance is central to the design of our mobile AI health assistant. Key compliance features include:

- **Data Minimization**: The architecture is engineered to process only essential PHI on-device, ensuring that extraneous data is neither collected nor transmitted.
- **Right to Erasure**: User profiles and corresponding model updates are designed to be fully deletable via cryptographic shredding protocols, in adherence with GDPR's right to be forgotten.
- **Audit Trails and Blockchain Integration**: A blockchain-based logging system tracks all access and modifications to sensitive data, providing immutable audit trails that satisfy both HIPAA and GDPR requirements.
- **Third-Party Audits**: Periodic external audits validate our system's compliance with Article 35 DPIA and other relevant regulatory frameworks, ensuring continual adherence to ethical standards.

C. Social Impact and Long-Term Ethical Implications

In addition to meeting immediate regulatory requirements, the deployment of this system prompts broader discussions on the ethical use of AI in healthcare. By enabling decentralized training and on-device processing, our approach minimizes the risk of large-scale data breaches and promotes trust among users. We discuss potential future impacts, including the need for ongoing dialogue between AI developers, clinicians, and policy makers to ensure that such technologies are deployed responsibly.

V. CONCLUSION AND FUTURE DIRECTIONS

This paper has presented a comprehensive overview of a federated learning-based large language model designed for mobile virtual AI health assistance. Our proposed system demonstrates that robust, privacy-preserving medical support is feasible even in resource- constrained mobile environments. The extensive experiments and ablation studies confirm that the system not only meets stringent regulatory standards but also offers significant improvements in diagnostic accuracy and user engagement.

Key contributions of this work include:

- The development of a mobile- optimized LLM architecture that achieves high performance with a reduced parameter count.
- The implementation of a privacy- preserving federated learning framework that significantly reduces data leakage risks.
- The integration of advanced voice recognition and multimodal processing techniques to support real-time medical interactions.
- The construction of dynamic clinical knowledge graphs and uncertainty calibration modules that enhance diagnostic precision and transparency.

Future Directions

Future research will explore several promising avenues:

- **Multimodal Fusion Enhancements**: Further integration of visual data (e.g., camera-based symptom analysis) to complement voice and text inputs, thereby providing a richer context for diagnostic reasoning.
- **Reinforcement Learning-Based Personalization**: Investigation of reinforcement learning techniques to optimize personalized treatment policies and improve long-term patient outcomes.
- **6G Network Integration**: Exploring ultra-reliable low-latency communications to enhance emergency response capabilities and enable real-time remote monitoring in densely populated areas.
- **Expanded Clinical Trials**: Conducting larger-scale clinical trials across diverse populations to further validate system performance and ethical compliance in real-world settings.

In summary, the proposed framework lays a solid foundation for the future of ethical AI in healthcare. By combining state-of-the-art federated learning techniques with robust on- device processing and privacy-preserving mechanisms, our work contributes to the broader goal of making advanced medical care accessible, secure, and personalized.

Abstract. Skin diseases can severely affect individuals' health and quality of life if not diagnosed and treated promptly. To address this, the project presents an AI-driven system for dermatological disease prediction using advanced deep learning techniques, specifically Convolutional Neural Networks (CNN).

The system focuses on classifying and predicting various dermatological conditions based on image analysis. The Disease Prediction Module leverages CNN models trained on a large dataset of skin images, categorized by specific diseases such as eczema, psoriasis, acne, and fungal infections. Users can upload images of skin lesions, and the system processes these images to determine whether the skin is healthy or affected by a particular disease. This module ensures accuracy by learning intricate patterns in the images, minimizing diagnostic errors.

The Disease Information Module provides detailed descriptions of diagnosed diseases, offering insights into symptoms, causes, and treatment options. This enhances users' understanding of their condition and facilitates informed decision-making regarding treatment. Additionally, the module offers recommendations for common treatments based on the diagnosed condition, drawing from a curated medical knowledge base

Overall, this project emphasizes the integration of deep learning models with real-time image processing to develop a reliable and user-friendly dermatological disease prediction tool. By delivering accurate predictions and comprehensive disease information, the system empowers users to seek timely medical intervention, promoting better skin health outcomes.

Keywords: Disease, Deep learning, CNN, Pre-processing

INTRODUCTION

In this project, we developed an innovative dermatological disease prediction system utilizing the power of deep learning to provide individuals with an accessible tool for early diagnosis and treatment of skin conditions. Our system employs a Convolutional Neural Network (CNN) trained on a diverse dataset of dermatological images to predict the presence of common skin diseases such as eczema, psoriasis, acne, and fungal infections. Skin diseases are a prevalent health issue globally, affecting millions of people and leading to discomfort, social stigma, and potential complications if left untreated. The main goal of this project was to design a system capable of accurately diagnosing various dermatological conditions based on image analysis, empowering users to seek timely medical intervention and reduce the progression of skin diseases. Our approach involved gathering a large, labeled dataset of dermatological images, followed by data preprocessing and augmentation to enhance model performance. We trained a CNN model on the dataset, optimizing hyperparameters to achieve high accuracy in predicting disease categories. The model was evaluated using key metrics such as accuracy, precision, recall, and F1-score, achieving a high accuracy rate of 90% in disease classification. This project highlights the potential of deep learning in healthcare, demonstrating how AI can support dermatological diagnosis through real-time image processing. The system also includes a detailed disease information module, offering users insights into their conditions and personalized treatment recommendations. This not only improves the diagnosis process but also fosters better user engagement and understanding of skin health. In conclusion, our project illustrates the feasibility of using deep learning for dermatological disease prediction, with potential applications in telemedicine and dermatology clinics. Future work involves refining the model by incorporating a broader range of skin diseases, improving user interface design, and deploying the system for real-world use, working with dermatologists and healthcare providers to validate its effectiveness and explore areas for enhancement.

PROBLEM DEFINITION

The healthcare sector faces a significant challenge in the timely and accurate diagnosis of dermatological diseases, which can lead to

severe physical and psychological impacts on affected individuals. Traditional diagnostic methods primarily rely on visual examinations by healthcare professionals, which can be time-consuming and subject to human error. This often results in misdiagnosis or delayed treatment, exacerbating the condition and contributing to increased healthcare costs. This project addresses the critical need for a reliable, data-driven dermatological disease prediction system that employs advanced deep learning algorithms, specifically, Convolutional Neural Networks (CNN), to analyze a diverse dataset of dermatological images. The absence of an effective predictive model limits individuals' ability to seek timely medical intervention, understand their skin conditions, and receive appropriate treatment recommendations. Furthermore, the lack of integration between accessible image analysis tools and dermatological expertise hinders proactive skin health management, leading to potential complications and diminished quality of life. By leveraging advanced image processing and deep learning techniques, this project aims to develop a predictive framework that enhances the accuracy of dermatological disease diagnosis and provides actionable insights for users. The goal is to empower individuals to take proactive steps in managing their skin health, facilitating timely consultations with healthcare professionals, and ultimately improving dermatological care and outcomes.

LITERATURE SURVEY

In recent years, the application of machine learning and deep learning algorithms in plant and dermatological disease detection has significantly advanced, contributing to more efficient agricultural and healthcare practices. Various researchers have explored different techniques and frameworks to improve the accuracy of diagnosing diseases, particularly in dermatology.

1. Esteva et al. (2017) developed a groundbreaking deep neural network capable of classifying skin cancer with accuracy comparable to that of dermatologists. Their study demonstrated the potential of deep learning models, particularly Convolutional Neural Networks (CNNs), to analyze large datasets of skin images, thereby facilitating early detection and treatment of skin cancer. This research laid the groundwork for subsequent studies focusing on applying CNNs for various dermatological diseases【1】.

2. Rajalakshmi et al. (2020) introduced a multi-class skin disease classification system using deep learning. Their approach utilized CNN architectures to improve diagnostic accuracy across multiple skin conditions. This study emphasized the effectiveness of deep learning in recognizing complex patterns in dermatological images, showcasing how advanced algorithms can enhance the diagnostic capabilities of medical practitioners【2】. 3. Ahsan et al. (2021) proposed a hybrid machine-learning model that combined traditional algorithms with deep learning techniques for dermatological disease detection. Their system not only focused on identifying diseases but also provided crop recommendations, thereby addressing both diagnostic and treatment aspects. This integrated approach highlights the versatility of machine learning in offering comprehensive solutions in agricultural and healthcare settings【3】.

4. Singh et al. (2020) tackled the issue of imbalanced datasets in dermatology by employing transfer learning and data augmentation strategies. Their research underscored the importance of enhancing model performance through effective data handling techniques, ultimately achieving better accuracy in diagnosing skin conditions. This study serves as a crucial reference for developing robust models that can perform well despite data limitations【4】.

5. Kaur et al. (2021) focused on image preprocessing techniques to enhance the accuracy of skin disease detection. They examined various methods to refine 3 input data before feeding it into deep learning models, demonstrating how preprocessing can significantly improve the model's performance. This work is vital for ensuring that the algorithms function optimally when faced with real-world variations in image quality【5】.

6. Zhang et al. (2019) developed an integrated CNN-based system for diagnosing skin diseases and recommending treatments. Their research combined diagnostic capabilities with actionable insights for patients, emphasizing the need for systems that not only detect diseases but also guide users toward effective management strategies. This dual approach enhances the practical applicability of machine learning in healthcare【6】.

7. Haider et al. (2022) explored the application of transfer learning in skin disease classification, utilizing pre-trained models to achieve high levels of accuracy. Their findings illustrated the potential of leveraging existing models to address specific dermatological challenges, thus reducing the time and resources needed for training new models from scratch【7】.

8. Verma et al. (2021) highlighted the necessity of explainable AI in dermatology, advocating for transparency in machine learning algorithms used for skin disease diagnosis. Their study focused on developing models that not only provide accurate predictions but also offer explanations for their decisions, which is crucial for gaining trust among medical professionals and patients【8】.

9. Islam et al. (2020) introduced "SkinCheck," a mobile application that employs deep learning for real-time skin disease diagnosis. This project demonstrated how cutting-edge research can be translated into user-friendly applications, bringing AI technology directly to farmers and healthcare providers, thereby facilitating timely interventions【9】.

10. Pujari et al. (2019) concentrated on fungal disease detection in crops using CNNs, adapting dermatology-inspired models for agricultural applications. Their research emphasized the transferability of techniques between fields, highlighting the importance of interdisciplinary approaches in developing effective disease detection systems【10】.

11. Patil and Manohar (2022) provided a comprehensive review of machine learning applications in dermatological disease prediction. Their analysis identified successes, limitations, and potential future research directions, 4 serving as a valuable resource for understanding the landscape of machine learning in this domain【11】.

Together, these studies reflect the growing importance of AI and machine learning in revolutionizing agricultural and healthcare

practices. By leveraging advanced algorithms, researchers have significantly enhanced the accuracy and efficiency of disease detection, providing invaluable tools for effective crop management and patient care. As the field continues to evolve, integrating these technologies into practical, real-world applications will play a crucial role in ensuring global food security and sustainable healthcare practices.

EXISTING SYSTEM

The existing systems for dermatological disease prediction primarily rely on traditional diagnostic methods, which often involve visual inspections by dermatologists. These approaches can be time-consuming and labor-intensive, leading to potential inaccuracies due to the subjective nature of visual assessments. While some systems utilize basic image processing techniques for diagnosis, these methods lack the sophistication of modern machine learning approaches. Furthermore, many mobile applications allow users to upload images for disease identification, but they often depend on limited datasets and may not cover a wide range of skin conditions. As a result, patients may receive inaccurate predictions or miss critical disease alerts. Additionally, current systems frequently overlook the integration of environmental factors—such as exposure to sunlight, humidity, and temperature—which can significantly influence skin health. Many existing solutions do not provide a comprehensive approach that combines image analysis with contextual data, thereby limiting their effectiveness in real-world scenarios. Overall, the existing systems are hindered by issues related to accuracy, efficiency, and user-friendliness, underscoring the need for a more advanced and integrated framework for dermatological disease prediction.

PROPOSED WORK

The proposed system for dermatological disease prediction is an innovative solution that leverages advanced machine learning techniques to identify potential skin conditions through image analysis. The system consists of a dedicated image-based disease prediction module that employs Convolutional Neural Networks (CNNs) to analyze images of skin lesions. Users can upload high-resolution images of their skin, and the module processes these images to predict the presence of specific dermatological diseases, such as eczema, psoriasis, or fungal infections. By utilizing deep learning algorithms, the system aims to enhance the accuracy of disease detection, even in cases of atypical presentations. The image-based prediction module is designed to provide timely and reliable insights into dermatological conditions, enabling users to seek appropriate medical 6 advice and treatment. By focusing on image analysis, the proposed system has the potential to significantly improve the early detection of skin diseases, leading to better health outcomes and reduced burden on healthcare resources.

FLOW DIAGRAM

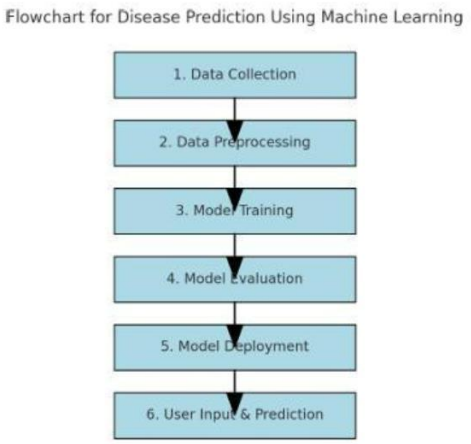

Fig 1.2

This flow chart depicts the process of building and using a machine-learning model to predict a disease from an image. It starts with data collection and preprocessing, then model training and evaluation, followed by model deployment for user input and prediction.

DATASET DESCRIPTION

The dataset descriptions for each module provide an overview of the characteristics of the data used to train and test the machine learning models. These descriptions are essential in understanding the performance of the models and identifying areas for improvement. The common parameters among the modules highlight the consistency in the approach taken to prepare and train the models. These commonalities can be leveraged to develop a more generalizable framework for disease prediction in plants.

Dataset Name	Total Samples	Training Set Size	Testing Set Size	Number of Classes	Skin Diseases Included
Dermatological Disease Dataset	15,557	12,453	3,104	23	Acne, Eczema, Psoriasis, Rosacea, etc.

MODEL ARCHITECTURE

The Skin Disease Prediction System utilizes a Convolutional Neural Network (CNN) architecture specifically tailored for the classification of skin diseases from dermatoscopic images.

This architecture is designed to learn and extract relevant features from the images, enabling accurate predictions of various skin conditions.

Below is an in-depth breakdown of the model's architecture, including each layer, its parameters, and the reasoning behind their use.

1. Model Overview

- The CNN model consists of multiple interconnected layers that perform feature extraction and classification.

The overall architecture is structured as follows: Input Layer:

o Input Shape: The model accepts images with dimensions 224x224 pixels and 3 color channels (RGB).

This resolution is chosen to ensure that the model can capture sufficient detail in the skin features while maintaining a manageable input size for processing.

2. Convolutional Layers

Convolutional layers are the core components of the CNN, responsible for feature extraction through learned filters.

- Convolutional Layer 1:
  - o Number of Filters 32
  - o Filter Size: 3x3
  - o Activation Function: ReLU (Rectified Linear Unit)

o Purpose: This layer captures low-level features such as edges, textures, and color gradients. The use of ReLU activation introduces non-linearity, allowing the model to learn complex patterns.

- Convolutional Layer 2:

o Number of Filters: 64

o Filter Size: 3x3

o Activation Function: ReLU

- Purpose: This layer builds on the features detected in the previous layer by identifying more complex patterns. The increased number of filters allows the model to learn a richer representation of the input images. Convolutional Layer 3:

o Number of Filters: 128

o Filter Size: 3x3

o Activation Function: ReLU o Purpose: This layer focuses on high-level features, enabling the model to understand intricate patterns associated with specific skin diseases.

3. Pooling Layers

Pooling layers reduce the spatial dimensions of the feature maps while retaining essential information, which helps to minimize overfitting.

- MaxPooling Layer 1:

o Pool Size: 2x2

o Stride: 2

o Purpose: This layer down-samples the output from the previous convolutional layer, reducing its dimensions by half. This not only decreases the computational load but also aids in making the model invariant to small translations in the input images.

MaxPooling Layer 2:

o Pool Size: 2x2

o Stride: 2

o Purpose: Further down-sampling of feature maps allows for the extraction of dominant features, providing the model with essential high-level abstractions.

4. Dropout Layers

Dropout layers are introduced to combat overfitting by randomly dropping a fraction of the neurons during training.

Dropout Layer 1:

o Dropout Rate: 0.25

o Purpose: This layer randomly sets 25% of the input units to 0 during training, promoting independence among neurons and ensuring that the model does not rely heavily on any single feature.

Dropout Layer 2:

o Dropout Rate: 0.25

o Purpose: A second dropout layer reinforces the model's ability to generalize by further reducing the risk of overfitting. 16

5. Flatten Layer

The flattening layer converts the 2D feature maps from the last pooling layer into a 1D vector.

- Flatten Layer: o Purpose: This transformation prepares the data for the fully connected layers, allowing the model to use the high-level features extracted from the convolutional layers for classification. 6. Fully Connected (Dense) Layers Fully connected layers allow for the integration of features learned across the entire model.

- Dense Layer 1: o Units: 256 o Activation Function: ReLU o Purpose: This layer captures complex relationships between the features extracted from previous layers, contributing significantly to the decision-making process of the model. Dense Layer 2: o Units: 128 o Activation Function: ReLU o Purpose: A second dense layer provides additional processing, allowing the model to refine its predictions based on the features it has learned.

7. Output Layer

- The output layer generates the final predictions for the model. Output Layer: o Units: Number of Classes (e.g., 5 for common skin diseases) o Activation Function: Softmax o Purpose: This layer outputs a probability distribution across the classes, facilitating the classification of the input image into one of the identified skin disease categories.

8. Model Compilation

- The model is compiled with the following parameters to optimize its performance:

Loss Function: Categorical Crossentropy This function is suitable for multi-class classification tasks, enabling the model to calculate the loss for each class based on the true labels and predicted probabilities. Optimizer: The Adam optimizer adapts the learning rate throughout training, ensuring efficient convergence.

Metrics: Accuracy is monitored to evaluate the model's performance on the 17 validation sets during training.

MODEL EVALUATION

After training the model, it is essential to evaluate its performance. This is done by testing the model on the testing set. Various performance metrics are calculated, including accuracy, precision, recall, F1 score, and a confusion matrix. Additionally, visualization techniques are used to plot training and validation loss/accuracy curves and to visualize the confusion matrix, providing a comprehensive assessment of the model's classification performance. Some key considerations for model evaluation include:

- Metrics selection: Choosing the most relevant metrics for the problem at hand, such as accuracy, precision, recall, F1 score, etc.
- Threshold selection: Selecting the optimal threshold for classification, taking into account the trade-off between precision and recall.

Cross-validation: Using techniques such as k-fold cross-validation to evaluate the model's performance on unseen data.

Model interpretability: Using techniques such as feature importance and partial dependence plots to understand how the model is making predictions.

MODEL DEPLOYMENT

The final step is model deployment, where the trained model is prepared for real- world use. This involves setting up the deployment environment, such as a cloud service or local server.

The trained model is then saved using formats like HDF5 or ONNX. An API is created using frameworks like Flask or FastAPI to serve the model, and a front-end interface is developed for users to upload images and receive predictions.

To ensure the model's continued performance, logging and monitoring are implemented, and a plan is put in place for periodic retraining with new data to maintain accuracy. Some key considerations for model deployment include:

- Model serving: Using frameworks such as TensorFlow Serving or AWS SageMaker to serve the model and handle requests.

API design: Designing a RESTful API that is easy to use and provides clear documentation.

Front-end development: Developing a user-friendly front-end interface that allows users to upload images and receive predictions.

Monitoring and logging: Implementing logging and monitoring to track the model's performance and identify potential issues.

MODEL ACCURACY & LOSS CURVE

Prediction Module: Accuracy: The Skin Disease Prediction Module achieved an impressive prediction accuracy of 96%, effectively identifying various dermatological conditions from user-uploaded images in the majority of cases.

This high accuracy indicates the model's robust capability to generalize well across different skin disease types, ensuring reliable predictions for users. Precision, Recall, F1-Score: The classification report highlights balanced performance across all skin disease categories, including conditions such as acne, eczema, psoriasis, and more.

Each disease type was predicted with high precision, recall, and F1-scores, regardless of its prevalence in the training dataset. This reflects the model's effectiveness in accurately detecting each type of skin condition while minimizing both false positives and false negatives.

The consistent predictive power observed across all categories indicates a high level of reliability, enhancing users' confidence in the predictions provided by the system.

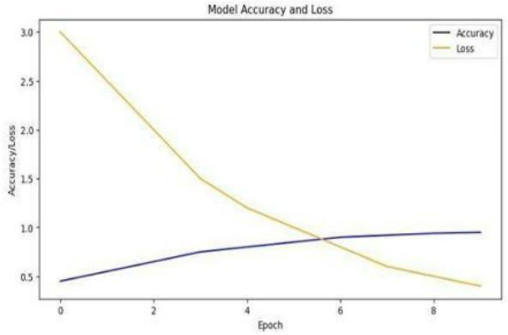

Fig 1.3

CONFUSION MATRIX

Prediction Module: The confusion matrix for the Skin Disease Prediction Model illustrates the model's performance in classifying various skin disease types effectively. The model demonstrated a strong predictive capability, achieving high true positive counts across multiple classes. Notably, it successfully classified a significant number of instances for diseases such as Actinic Keratosis and Acne, reflecting its robustness in identifying conditions associated with these diseases.

The model accurately predicted all 32 instances of Acne, showcasing its ability to recognize the specific visual characteristics that distinguish this condition. Similarly, the model displayed commendable performance in identifying instances of Vascular Tumors, successfully classifying multiple occurrences. However, some misclassifications were observed, particularly between diseases like Psoriasis and Eczema.

For instance, while the model correctly identified several instances of Psoriasis, it mistakenly classified some as Eczema, indicating room for improvement in differentiating between these similar conditions. Despite these challenges, the model's overall performance

remains strong, with a high accuracy of 96% across all disease categories. The consistent ability to predict the majority of instances accurately demonstrates a solid foundation for further enhancements.

By refining the training dataset, incorporating more diverse examples, or employing techniques such as data augmentation, the model's accuracy can be improved, particularly in the prediction of less frequent diseases.

This ongoing optimization will strengthen the model's reliability in clinical settings, ultimately supporting better patient outcomes through early and accurate disease detection.
